In the past eight years, epidemics of poliomyelitis have appeared in the South and Southeast for the first time notably in the Carolinas, Florida, Alabama and Mississippi. With the exception of California, the states of the Southwest have generally escaped epidemics of any size and the state of Texas in particular has been relatively free of the disease. In 1916 there were only 63 cases reported in the entire state. In 1935 there were 78, in 1936 there were 65 cases and in 1937 there were 637 cases though these were widely scattered through the north central part of the state and were not numerous in the cities. In the next year 1938 only 60 cases were reported and in 1940 there were 161 cases. The Texas cities have been com-

Chart 1—Time of occurrence of acute cases of poliomyelitis in San Antonio during the 1942 epidemic

paratively free of the disease except for 58 cases observed in Fort Worth in 1927. San Antonio at no time has had over 10 cases in a single year.

In the fall of 1942, however, 87 cases of poliomyelitis were seen between Sept. 26, 1942 and Jan. 19, 1943 in persons who resided in the metropolitan area of San Antonio. An even more severe outbreak occurred simultaneously at Corpus Christi, 150 miles to the southeast. Before Sept. 26, 1942 only 2 sporadic cases had been observed in San Antonio during the entire summer "polio season." After Sept. 26, 1942 cases began to appear in the frequency shown in chart 1.

Reports of "winter epidemics" of poliomyelitis have been made in the past but it must be borne in mind that San Antonio winters are mild and, as chart 2 shows, the fall and winter months of 1942 were quite warm. In October, November and December the daily temperatures ranged in the 80's and on only one night was the minimum temperature as low as 26 F. Consequently the period under consideration was climatically very similar to the northern late summer season.

San Antonio is normally a city of 260,000, but the present population with the large army and air force concentrations reaches well over 400,000. This more-

than 50 per cent rapid increase in population has thrown unusual demands on water supply systems, sewage disposal facilities, housing and all public health activities. This might of itself favor the outbreak of epidemic diseases and especially the so-called intestinal diseases.

Of the 87 patients with poliomyelitis there were 46 males and 41 females. They were divided among the racial groups as follows: Anglo-Americans, 63 cases,

TABLE 1—Ages of Patients with Poliomyelitis

Under 1 year of age	6 cases
1-5 years of age	46 cases
5-10 years of age	17 cases
10-15 years of age	5 cases
15-20 years of age	5 cases
20-25 years of age	6 cases
25-30 years of age	1 case
30-35 years of age	0 cases
35-40 years of age	1 case
Total	87 cases

Mexicans 20, Italians 2, Negroes 2. This corresponds roughly with the proportions of the various racial groups in the San Antonio population (1940 census: Anglo-Americans, 56 per cent; Mexicans, 34 per cent; Negroes 7 per cent; Italians 2 per cent).

The ages of the patients with poliomyelitis varied from eight months to thirty-eight years and were distributed as shown in table 1. As can be seen approximately 60 per cent of the patients were 5 years of age or less and nearly 80 per cent of the patients were less than 10 years of age.

The signs and symptoms which led to the diagnosis of poliomyelitis were fever, headache, stiff neck, stiff back and muscular weakness. Sixty-two of the patients were of the paralytic type and showed definite muscular weakness. The remaining 25 patients were "abortive" and showed no muscular weakness at the end of the acute state of the illness. With few exceptions we examined every patient in this group and numerous others who were poliomyelitis suspects, but in this statistical study we are including only those cases in which the diagnosis could be made with certainty. Routine spinal fluid examinations were not made in

TABLE 2—Principal Paralysis of Sixty-Two Patients with Muscular Weakness

Left leg	24 cases
Right leg	19 cases
Both legs	11 cases
Left arm and shoulder	10 cases
Right arm and shoulder	3 cases
Both arms	4 cases
Facial weakness	6 cases
Bulbar type paralysis	7 cases (6 deaths)

all cases because we felt that the diagnosis was sufficiently clear in many to eliminate the necessity for it. Moreover, in those cases in which stiffness of the back was pronounced we felt that the procedure was too painful for the little additional diagnostic advantage gained. Of the spinal fluid examinations which were made we found the usual increase in protein content and cell counts ranging from 10 to 220.

The principal paralysis of the 62 paralytic patients who presented muscular weakness as a prominent symptom are given in table 2. Of course, the pattern

of paralysis was exceedingly varied and some patients showed several extremities involved, which explains the discrepancy between the number of patients and the number of paralyzed extremities. As is generally true, nearly all the patients with bulbar paralysis died despite the use of the respirator and other supportive measures. Two patients showed the polyneuritic type of poliomyelitis in which there was severe pain and tenderness of the legs which persisted for many weeks.

As soon as it became apparent that many acute cases of poliomyelitis were developing, the Robert B. Green (City-County) Hospital established a poliomyelitis ward and an isolation unit. Physical therapy technicians specially trained in the Kenny method of treatment were secured through the local chapter of the National Foundation for Infantile Paralysis and the

As a measure for retarding spread of the epidemic we advised the families of patients to fill the house where the patient lived with insect spray and to repeat it

TABLE 3—After Effects

before the quarantine was lifted. It was recommended that other children who lived in the house or nearby should have oil of citronella applied to exposed skin

Chart 2—Daily maximum and minimum temperatures in San Antonio October-December 1942 Prepared from United States Weather Bureau statistics

Texas State Crippled Children's Bureau During the time of the outbreak, 39 cases were treated in the hospital by the Kenny trained physical therapists. In other words, all patients who showed any muscle tenderness or weakness, stiffness of the back or hyper-tonicity of muscles were given the treatment as outlined by the Minneapolis group. Moreover, intensive treatment was abandoned only when all muscle hyper-irritability and pain were overcome

surfaces when playing outdoors or when in public places. While patients were in the hospital and for two months after going home, a tablespoon of phenol was placed in bowel movements (in bedpans) and allowed to remain fifteen minutes before emptying in the toilet. On Jan. 21, 1943 we reexamined all the patients and collected reports on every one who had had acute poliomyelitis to determine the extent of their recovery up to that time. Thirty patients were free from all effects

of the disease with no muscle weakness or residual hypertonicity of any muscle groups. These included the 25 cases which were considered to be abortive or which showed only slight temporary muscular weakness. The results of the examinations made immediately after the epidemic are given in table 3. At the time of reexamination there were no joint deformities or muscle contractures in those patients who had been treated by the Kenny method. Two who had refused treatment showed considerable muscle contracture and beginning deformity. Also none of these patients had developed definite sympathetic changes (discoloration, cold clammy skin and extensive atrophy) in the involved extremities.

As stated before there was a relatively severe outbreak of poliomyelitis in Corpus Christi, Texas, during the time of the San Antonio epidemic and we saw 15 patients with poliomyelitis who resided in towns adjacent to San Antonio that are not included in this series.

Through the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army Dr. John R. Paul, professor of preventive medicine in the Yale University School of Medicine and director of the Commission on Neurotropic Virus Diseases was sent to San Antonio in December 1942 to study the course of this epidemic. In his report to the Surgeon General's Office these epidemiologic observations were made:

In keeping with the experience of other southern epidemics which have occurred since 1938 the age group in the San Antonio cases was lower than the average age group in northern epidemics.

Several cases occurred in children who had just recently moved to San Antonio and in 1 instance the child had been in the city only five days before developing the disease.

From stool specimens of the San Antonio patients a typical strain of the poliomyelitis virus was isolated.

Sewage and sludge samples collected at the city sewage disposal plant were negative for evidence of the poliomyelitis virus.

From flies collected in homes of patients with poliomyelitis a strain of poliomyelitis virus was isolated.

SUMMARY

1 The 1942 poliomyelitis epidemic in San Antonio has been studied by our personal observation of all the patients who were known to have the disease.

2 The 87 patients were with few exceptions treated by the Kenny method and a follow-up examination revealed more rapid recoveries than usual among those who were not severely paralyzed at the onset. Observations indicate that there will be less residual deformity among these patients than is usually observed.

3 The 1942 epidemic in San Antonio occurred principally in October, November and December, whereas the normal peak months of epidemics elsewhere are June, July and August.

4 The age incidence of the patients in this epidemic was lower than is usual in northern epidemics but was in keeping with experience during other outbreaks in the South.

5 Careful epidemiologic studies were made in San Antonio during the epidemic by Dr. John R. Paul and the findings were reported.

BACTERIAL CONTAMINATIONS IN SULFONAMIDE OINTMENTS

C VIRGINIA FISHER, PH.D.

N. J. ACCOUSTI, PH.G., CH.E.

AND

MARVIN R. THOMPSON, PH.D.

NEW YORK

That sulfonamide compounds in themselves are bacteriostatic rather than bactericidal agents in vitro is an established fact.¹ The rapidly growing medical use of sulfonamide powders, ointments and solutions for topical application in superficial and deep wounds raises the question of the possibility of their becoming contaminated with pathogenic organisms not affected by the drugs.

Recent findings have shown some products so contaminated. Our experiments have led us to believe that serious contaminations do occur. Welch, Slocum and Herwick² have emphasized the necessity for sterilization of sulfonamide dusting powders since these powders were incapable of killing tetanus spores with which they were contaminated. Recently a report³ has come from

Experiments using the agar cup plate test⁴ indicate that ointments prepared in a water dispersible base⁵ with 5 per cent sulfanilamide, sulfathiazole or sulfadiazine

The use of urea to increase the rapidity of wound healing has been advocated⁶

Oxidizing agents seemed to offer promising possibilities for increasing the bactericidal activity of the sulfonamide ointments in vitro. Further studies were conducted therefore with benzoyl peroxide, urea-hydrogen peroxide (hereinafter referred to as urea peroxide) and zinc peroxide

ous oxidizing agents the following test was devised. Four Gm of the ointments was weighed into sterile glass jars and 1 cc of a twenty hour broth culture of the desired test organism was thoroughly mixed with the ointment. Subcultures consisting of a 4 mm loopful of the ointment-organism mixture into nutrient or defibrinated blood broth mediums were taken at the time intervals indicated in the accompanying tables. In all instances, presence or absence of growth was checked after twenty-four hours incubation at 37 C of the original subcultures by smear, or by plating on nutrient or blood agar plates. Tables 3, 4 and 5 show the results obtained when the ointments were contaminated with *Staphylococcus aureus* No. 209, *Streptococcus hemolyticus* C-203 and *Escherichia coli* (acid lactici strain).

Clostridium tetani (Lister strain)¹⁰ and *Clostridium perfringens* (Barber strain)¹⁰ were selected to determine the ability of these ointments to reestablish sterility.

when contaminated with anaerobic spore forming organisms. A spore suspension of *C. tetani* was prepared according to the method of Bliss, Long and Smith.¹¹

10. Cultures were obtained through the courtesy of Dr. John C. Torrey, Cornell Medical College, New York City.

11. Bliss, Eleanor V., Long, P. H., and Smith, Dorothy G. Chemotherapy of Experimental Gas Gangrene and Tetanus. In: *Annals of the New York Academy of Medicine*, 1941, 310 (Nov.) 1941.

One cc of the spore suspension was mixed with 4 Gm of the ointment, and subcultures into thioglycolate mediums were made as described for *Staphylococcus*, *Streptococcus* and *E. coli*. The subcultures were incubated for forty-eight hours and growth was checked by smears. Table 6 presents the results of these tests.

To test further the cultural and functional findings, the contaminated ointments were injected into guinea pigs. Serial dilutions of the spore suspension were made. Injections of these into guinea pigs showed that a 1:10 dilution of the suspension was equivalent to approximately 10 minimum lethal doses. Four Gm of the ointment was weighed out and thoroughly mixed with 1 cc of the undiluted spore suspension. After being allowed to stand for twenty-four hours, the ointment-spore suspension mixtures were mixed with 5 cc of a sterile 5 per cent calcium chloride solution, making the final dilution of the spore suspension 1:10. Five-tenths cc of the resultant mixture was injected into the right hind leg muscle of guinea pigs weighing from 250 to 275 Gm (table 8).

Three strains of *Clostridium perfringens* (type I, type II and Barber) which were studied did not sporulate readily. Further studies of this organism were made with vegetative forms grown for twenty hours in thioglycolate mediums, centrifuged, washed and resuspended in 2.5 per cent calcium chloride solution. The minimum lethal dose for the Barber strain was determined to be approximately the same as for *Clostridium*

studied, the most practical and generally effective agent to insure safety and therapeutic performance appears to be urea peroxide in up to 1 per cent concentration. Higher concentrations increase the irritant properties to an objectionable degree for certain uses.

3. These findings emphasize the importance of care in the manufacture of sulfonamide products intended for topical application. The addition of an antiseptic to enhance the bactericidal properties and insure sterility of sulfonamide ointments is indicated to be essential as a factor of safety.

POSTERIOR HERNIA OF THE KNEE

(BAKER'S CYST, POPLITEAL CYST, SEMIMEMBRANOSUS BURSITIS, MEDIAL GASTROCNEMIUS BURSITIS AND POPLITEAL BURSITIS)

HENRY W. MEYERDING, M.D.

AND

ROBERT E. VANDEMARK, M.D.

Fellow in Orthopedic Surgery, Mayo Foundation
ROCHESTER, MINN.

The differential diagnosis of benign and malignant popliteal tumors, aneurysms, varicosities, bursae and posterior perforations of the synovia of the knee joint frequently taxes the ability of the physician. This paper is based on a series of 15 cases in which popliteal cysts produced firm fixed masses and, in some instances, limitation of flexion of the knee and swelling in the popliteal space. Surgical intervention revealed that each of these cysts was connected directly with the knee joint through an opening in the posterior part of the capsule, usually along the lateral side of the medial condyle of the femur. We believe that these cysts are the result of (1) herniation of the synovial membrane through the posterior part of the capsule or (2) the escape of fluid through the normal anatomic connections of the knee joint into the bursae, that is, into the medial gastrocnemius or semimembranosus bursae. In this study we have considered Baker's cyst as an endothelial lined cyst which appears in the popliteal space and is connected with the joint.

Since in 1877, when Baker¹ published an article on synovial cysts of the knee, his name has been associated with these cysts. In 1840 Adams² described cystic swellings associated with chronic rheumatic arthritis of the knee. Gruber,³ who later became professor of anatomy at the university in St. Petersburg, described posterior hernia of the joint in 1845 and later distinguished it clearly from enlarged popliteal bursae not connected with the joint. In the experience of Baker¹ and others, in the days of laudable pus, surgical intervention on the cysts frequently resulted in septic arthritis and amputation, but with the development of aseptic technic infection became rare and amputation seldom became necessary. The value of injection of air into

the knee in making the diagnosis of Baker's cyst before operation was clearly demonstrated by Cravener⁵ in 1932. In 1938 Haggart⁶ reported several cases of posterior hernia of the knee and Wilson and his associates⁷ reported a number of cases of popliteal bursae connected with the joint.

ETIOLOGIC CONSIDERATIONS

Certain anatomic factors at the knee predispose to posterior hernia. At operation it has been noticed that the capsule is weak along the lateral side of the medial condyle of the femur. Each of the most important bursae of the popliteal space, that is, the semimembranosus, the semitendinosus, the popliteus and the gastrocnemius bursae (fig 1) may communicate with the joint as well as with one another under certain conditions. Synovial diverticula may herniate through the fibers of the oblique posterior ligament.⁸ The communications of these various structures with the joint are in many instances open when the knee is extended and the posterior part of the capsule tense but tend to close with flexion of the knee. Herniation and escape of synovial fluid into these structures thus increase with motion, and therefore the cyst enlarges. In the case of bursae, Wilson and his associates expressed the belief that the overlying muscles close the articular communication of the underlying bursae and distention of the bursae results. Because of the anatomic factors just mentioned we feel that trauma is not an etiologic factor. Rheumatoid arthritis and osteoarthritis have been reported in association with posterior hernia of the knee, and in 7 of our 15 cases rheumatoid and osteoarthritis were associated. The effusion associated with arthritis may perhaps have been of etiologic significance.

THE HERNIAL SAC

The hernial sacs are frequently 8 to 10 cm. in length and 5 to 7.5 cm. in width. When they enlarge they follow the path of least resistance and may extend downward as far as the achilles tendon as described by Boyd.⁹ The hernial sac is attached to the joint by a pedicle, which may become firm and thick and attain a length of 1 to 1.5 cm. and also may be densely adherent to the tendons, particularly the gastrocnemius. These bursa-like sacs may be multilocular and contain yellow tinged mucilaginous fluid, which may be either clear or clouded with fibrin. In severe popliteal injuries hemorrhage may occur into the sac or hemarthrosis may result. Occasionally an injury will cause rupture of the cyst, the surrounding structures then form the new wall of the hernial sac.

Microscopic examination of the intact hernial sac reveals an inner layer of endothelium, a subendothelial layer of definite infiltration of round cells and an outer layer of fibrous tissue which measures from 1 mm. to as much as 1 cm. in thickness at the pedicle and narrows distally. This outer layer contains dilated blood vessels. Hyaline and fibrocartilaginous metaplasia and hemosiderin may be present (figs 2 and 3).

SYMPTOMS

Symptoms of posterior hernia are usually not severe. In our experience disability has never been pronounced and symptoms of internal derangement of the knee have not been encountered. This experience is in direct contrast to that reported by Haggart. Our patients usually complained of aching and stiffness of the knee, and of tumor which caused them much concern. Examination usually revealed a tumor of variable size which is not painful or adherent to the overlying skin but may be firm on extension of the knee and softer on flexion. On flexion it may move side to side, but it has a fixed point at the capsule. The bulk of the tumor is usually distal to the flexion crease of the knee. In some cases fluctuation can be demonstrated.

Fig 1—Location of bursae with relation to the muscles of the popliteal space.

locally. Pulsation rarely is present in a distended cyst. Bruit and inguinal adenopathy are absent. The patient can walk and use the leg although there may be some limitation of flexion and rarely some disuse atrophy of the extremity. The popliteal swelling may decrease spontaneously, only to enlarge later and may be secondary to swelling resulting from arthritis of the knee. Although cases of bilateral Baker's cyst have been reported,¹⁰ the majority are unilateral.

In our series of 15 cases the left knee was affected in 9 cases, the right in 6. The age of our patients varied from 2 to 61 years. Eight of the 15 patients

¹⁰ Jefferson Geo. F. Bilateral Baker's Cyst. Recurrence After Operation. *Proc. Roy. Soc. Med. (Sect. for Study of Disease of Children)* 13: 162 (June) 1920.

were females. The duration of symptoms varied from four months to twenty years. Results of laboratory tests, including urinalysis, blood count, determination of the value of hemoglobin, Wassermann and the flocculation tests for syphilis were routinely negative. The sedimentation rate was elevated in some cases of arthri-

Fig 2—Baker's cyst (X 16)

tis. The roentgenogram revealed a tumor of soft tissue at the posterior aspect of the knee, arthritic changes were frequently present in the knee (fig 4).

DIAGNOSIS

The diagnosis of posterior hernia of the knee is not difficult if the condition is kept in mind. Transillumination reveals the uniform cystic character of the lesion, and aspiration demonstrates the fluid contents. A roentgenogram made after injection of 100 to 150 cc of air into the knee,¹¹ after aspiration of the synovial fluid, usually will reveal an air bubble in the hernial sac, thus connection is demonstrated with the joint. Wilson and his associates stated that occasionally when this procedure fails a roentgenogram made after aspiration of fluid and injection of air into the sac will reveal air in the joint. Injection of air was not employed in our series of cases. It is advisable to bear in mind the potential dangers of sepsis and pulmonary embolism when this procedure is carried out. The characteristic symptoms and findings, including transillumination are usually sufficient but, when doubt exists, roentgenograms made after injection of air into the joint will establish the preoperative diagnosis.

Benign tumors frequently are confused with the condition under consideration. Lipomas have a characteristic soft consistency, do not transilluminate, are usually painless and do not yield fluid on aspiration and therefore injection of air is not advisable. Lipomas may occur elsewhere in the body as multiple tumors. In contrast, xanthomas are of firm consistency, when they

are present the ratio of cholesterol to the cholesterol esters in the blood plasma is abnormal or the absolute values of each may be elevated. The mass does not transilluminate. Microscopic examination of frozen tissue may be necessary to establish the exact diagnosis. Enlarged popliteal bursae not communicating with the knee may be difficult to distinguish from those which do communicate with the knee, injection of air or surgical exposure may be necessary to establish the diagnosis.

The most common malignant tumor to be distinguished from cysts that communicate with the knee is fibrosarcoma, which is of a firm to hard consistency, is more fixed to the deep structures than a cyst and does not transilluminate. Pain and stiffness of the knee may be associated with progressive increase in size. Examination of frozen tissue may be necessary to establish its exact diagnosis. The vascular tumors of the popliteal space differ in many respects but are occasionally confused with Baker's cyst. Aneurysm, which is rare, is expansile and pulsating. It may increase in size and cause limitation of motion. The pulsations and bruit synchronize with the heart beat and are decreased when pressure is made on the femoral artery. Arteriovenous fistulas, which are rare, may have the same signs as aneurysm and in addition cardiac enlargement may be present. A history of trauma, Branham's brachycardia on compression of the femoral artery and circulatory deficiency distal to the fistula point to the correct diagnosis. Varicose veins are seen as soft, dark, tortuous fluidlike swellings, varicosities are usually present elsewhere on the extremity. Hemangioma appears as a soft, vaguely defined tumor with

Fig 3—Baker's cyst, same case as figure 2, an inner layer of the wall, a subendothelial layer in which round cell infiltration is pronounced and an outer layer of fibrous tissue (X 95).

increased local heat, dilated vessels may be seen locally or elsewhere in the body, and the roentgenogram may reveal calcification in the region of the tumor.

With popliteal lymphadenopathy a tender, firm, bean-shaped enlargement is present which does not transilluminate.

¹¹ Quaintance, P. A. Pneumoroentgenography of the Knee Joint. An Analysis of Fifty Cases, *J. Bone & Joint Surg.* 20: 353-362 (April) 1938.

illuminate. This subsides with the more distally located causative infection. In rare instances popliteal lymphadenopathy may be associated with lymphomas in other parts of the body.

Infectious swellings may be of the pyogenic or tuberculous type. Pyogenic abscess is characterized by local

remembered that, when arthritis is present, proper measures should be employed in its treatment, in addition to the treatment of the tumor.

TREATMENT

Surgical treatment is the method of choice and is indicated whenever symptoms are present. After application of a tourniquet an adequate longitudinal incision is made directly over the tumor and parallel to its course. The deep fascia then is divided and the hernial sac exposed. By means of blunt and later sharp dissection the hernial sac is exposed down to its attachment to the capsule. Flexion of the knee will at times facilitate exposure and aid in dissection. We have not found it necessary to divide the tendons. We feel that it is best to isolate the whole sac down to the pedicle, attachment of the capsule, clamp with a hemostat and divide, sufficient length is left to invert the pedicle after roughening its outer surface and applying tincture of iodine. We prefer to use permanent material, such as silk, for the purse-string suture on the pedicle. Simpler methods which may be used in the treatment of the pedicle are ligation alone or wide excision of the pedicle and leaving the capsule open. We feel however, that the latter procedure predisposes to recurrence. The only known recurrence in our series as well as in that of Wilson and his associates followed excision in which the capsule was not closed. After the sac is excised the wound is closed in layers, a firm dressing is applied and a padded posterior splint is used to immobilize the knee in extension (fig. 5).

"Quadriceps setting" exercises are begun on the second postoperative day. By the end of the first week the patient is allowed up and about the room and ten

Fig. 4—Large cystic mass at knee which at the time of operation was found to contain fluid and was connected directly with the joint (lateral view).

evidence of inflammation including tenderness and fluctuation. Fever, limited flexion of the knee, edema of the leg and inguinal lymphadenopathy usually are present, and culture of the pus obtained by aspiration usually reveals the causative organism. With tuberculous abscesses the signs of inflammation are usually minimal unless the abscess is secondarily infected, there is a history of exposure or evidence of tuberculosis elsewhere, biopsy or aspiration and inoculation of guinea pigs confirm the diagnosis.

Charcot's joint is an unstable enlarged joint which may be painful only at the onset of the disturbance. Serologic and neurologic studies confirm the diagnosis of syphilis or syringomyelia. The roentgenogram may reveal loose bodies posteriorly (simulating tumor), with a loss of joint margins, bony sclerosis and destructive arthritis.

PROGNOSIS

The prognosis in cases of Baker's cyst in which treatment is not given usually is unsatisfactory, for progressive enlargement occurs. With conservative treatment consisting of aspiration, rest and bandaging the prognosis is indeterminate. Careful dissection and ligation of the pedicle with the aid of modern aseptic technique is the treatment of choice, and recurrences of the cysts are rare.

The presence of arthritis greatly influences the ultimate restoration of normal function and it is to be

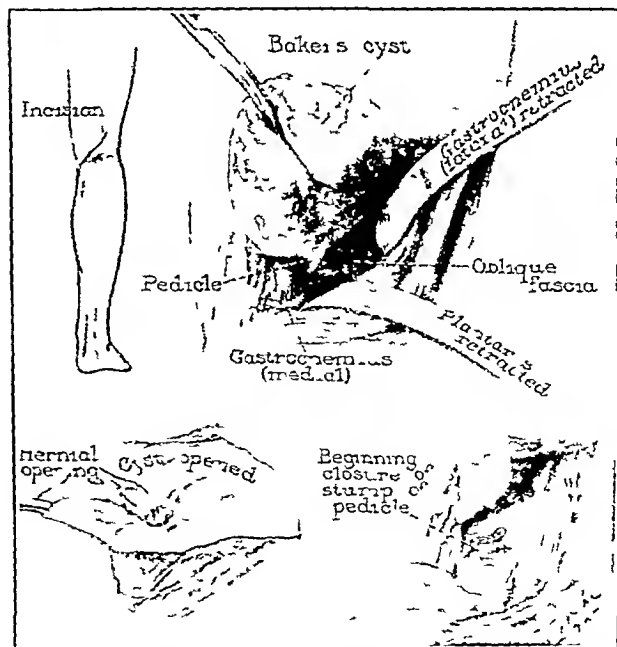

Fig. 5—The surgical technique employed: the oblique incision over popliteal space and along the course of the cyst; the cyst dissected free and pedicle exposed at the point of entrance into the joint; cyst opened to show inner surface and hernial opening into the joint and pedicle exposed after excision of cyst.

days after operation is walking without crutches. The sutures in the skin are removed on the fourteenth postoperative day, at which time the splint is discarded. Convalescence following operation has been entirely uneventful in our series.

FUNCTIONAL FACTORS IN COMMON DERMATOSES

MAXIMILIAN E OBERMAYER, M D

105 ANGLIS

During the past two decades the study of functional disease has been pursued with great energy and enthusiasm in all fields of clinical medicine. The most likely causes for the greater attention paid to the functional factors in disease are the considerably increased incidence of functional disease, the comparatively high stage of knowledge of organic disease that has been reached and the development of psychiatry.

The increased frequency of functional disease is apparent to even the casual observer. Some workers¹ have advanced the theory that nervous tension incident to the pressure and accelerated speed of modern living, especially under the highly artificial conditions in the big cities, is responsible, but this is only a partial explanation. The cause of the phenomenon is far more deeply rooted. The peoples of the Western World have long sensed and attempted to adjust to the approach of fundamental changes in their accustomed ways of living, changes which the present political events are bringing near the point of culmination. The nervous systems of generations which have the doubtful privilege of living through a violent phase of transition are bound to suffer not only from the resulting economic insecurity but from the multiple internal conflicts which necessarily arise when ideologic concepts, moral or otherwise, are subjected to rapid change. This is a neurotic age in which emotional tension has reached a degree probably unparalleled in history. It is no wonder that functional disease is flourishing and will continue to thrive until mankind has again found its balance and equilibrium has been restored, a goal which unhappily seems far distant indeed.

The enormous improvement that has taken place in the methods of diagnosis of organic disease, especially the high development of biologic chemistry, has made it possible to differentiate the organic from the functional symptom in a large majority of cases. An attempt at such differentiation twenty years ago would have been based on little more than guesswork. Not a small part of this progress is due to one of the newest fields of specialized medicine, namely allergy. It is a common misconception that allergy and the study of functional disease are antagonistic. On the contrary, allergy has provided bridges with which to span the apparent ravine between organic and functional disease, as will be illustrated later on.

Without the development of psychiatry and, subsequently, of the study of psychosomatic disorders, the investigation and understanding of functional disease would still be in their infant stage. The results of modern psychiatric progress are not of importance to the field of psychiatry or the study of mental diseases alone. What is of more immediate practical importance is that knowledge gained from psychiatric studies has been widely spread not only among psychiatrists but among the members of the rest of the medical world, including

the trained social worker as well, and the educated lay public has also been inculcated with psychiatric concepts of basic importance. Without this popularization of psychiatric facts, practical large scale application of psychotherapy in the widest sense would encounter far greater difficulties than it does today.

Recognition of the existence of functional factors has been prompt in many fields of medicine, though perhaps most particularly in gastroenterology and otolaryngology. Consequently such disorders as functional colitis and vasomotor rhinitis are familiar not only to the specialists most closely concerned with them but to the general practitioner as well. There is no hesitancy in including a discussion of the concepts of such functional disorders in lectures to students or in papers in medical journals designed for the general practitioner.

Peculiarly enough, the situation in dermatology is different. Whatever the explanation—and some interesting and logical speculations have recently been set forth by Stokes and Beerman²—the fact remains that the existence of functional dermatoses has been maintained only by a few research workers, while the great majority of dermatologists have refused to give it official recognition. The word "official" should be emphasized, because my colleagues and I, both in the Midwest and out here on the coast, have encountered patients who had been told by their physicians that their cutaneous disorders were psychogenic, while the same dermatologists would not support a functional cause of the condition in question on the lecture platform. It appears then that the existence of functional factors in some dermatoses is recognized to a fairly great extent in actual practice while the theory of functional causation is still refused by many. The result of this anomalous situation is that the spread of knowledge of functional disease in dermatology has been very slow. Most of the literature on the subject has been published only in journals designed for the specialist, and some has even appeared in more esoteric mediums available only to physicians who live in cities that are important medical centers. Papers by Klauder,³ Becker,⁴ Stokes,⁵ and Cormia and Slight⁶ are exceptions to the rule. Moreover, this dichotomy of attitude is responsible for the absence of information on functional disease from most dermatologic treatises designed for students and general practitioners.

Such an attitude of withholding information would be justified only if present day knowledge of functional factors in dermatoses were not sufficiently advanced to be of practical use, or methods of treatment based on this knowledge could not suitably be applied by the general practitioner. To dispose the validity of the two conditions is the object of my discussion.

INTERACTION OF MULTIPLE FACTORS

Conservative evaluation based on my own experience and on the published observations of others makes me believe that functional factors play a role in the following

ing dermatoses which are arranged in descending order according to the degree of demonstrable emotional disturbance

- Acarophobia
- Burning tongue
- Neurotic excoriations
- Dermatitis factitia (all cases in which self infliction purely for malingering purposes can be excluded)
- Generalized pruritus of nonorganic origin
- Localized pruritus of nonorganic origin
- Chronic recurrent urticaria (cases in which organic causes cannot be detected or in which the removal of supposedly causal organic factors does not result in cure)
- Chronic recurrent dyshidrosis of the hands and feet
- Neurodermatitis or atopic dermatitis
- Alopecia areata
- Rosacea
- Dermatitis herpetiformis and herpes gestationis
- Lichen planus
- Herpes simplex, especially herpes genitalis
- Chronic recurrent stomatitis aphthosa and its less superficial forms, periaadenitis mucosae chronica recurrens and ulcus neuroticum mucosae oris
- Lupus erythematosus (some cases)
- Psoriasis (some cases)
- Acne vulgaris (some cases)

As will be seen from this list these dermatoses cover a wide range of causes. Some, such as neurotic excoriations, are evidences of true neuroses. Some, such as urticaria, are considered allergic, in others, such as lupus erythematosus an infectious basis is recognized, and the cause of others, such as psoriasis, is still unknown.

Little need be said about the true dermatoneuroses. That they are psychogenic is generally recognized. But in the majority of dermatoses included in the foregoing list the functional or emotional factor is not solely responsible, it may not even play the most important role, it may form only one link in a chain composed of several causative elements of which the allergic, the bacterial and the toxic are perhaps the best recognized. Thus the etiologic situation in the so-called allergic dermatoses is more complicated. In conditions such as neurodermatitis or in some forms of chronic recurrent urticaria, it is well established that allergic phenomena, exemplified by positive dermal (scratch or intracutaneous) tests, usually polyvalent, are present, and full credit must be given to the allergist, whose studies have made it possible to view the allergic evidence in these cutaneous disorders in a new light. After clinical and experimental studies⁷ had made it clear that the causative role of the discovered allergens was questionable, it became possible to study the problem from a different angle. The results of these studies have substantiated the earlier concepts that patients with such disorders have an inherent, predisposing constitutional background. There is more and more evidence, furnished mainly by British and German observers, which indicates that hypersensitivity to certain allergens is not a constant phenomenon. The threshold of allergic response may be raised or lowered at a given time by the state of emotional tension. A patient may react to an allergen at one time but not at another. Becker and I⁸ have made similar observations. One of our patients with food urticaria could eat a certain food without difficulty while on his vacation but could not

eat it with impunity at home, even if the food had been obtained from the same source and was apparently unaltered. Another example is furnished by a child whose asthma and dermatitis was aggravated by the ingestion of fish, to which he was allergic, the same fish, however, did not elicit any reactions under conditions prevailing in a sanatorium.⁹ The allergic background of such patients is an inherited and therefore unchangeable feature, but the allergic reactivity of the skin can be modified by emotional factors. For example, a patient with food urticaria may be able to eat the food to which he is hypersensitive when he is free from tension and anxiety. Dunbar¹⁰ has shown that symptoms may be eliminated by psychotherapy while the cutaneous reactions to the specific substances remain unchanged. On the other hand, it has been suggested by experiments¹¹ that intense emotional conflict may produce hypersensitivity to substances not generally pathogenic, a phenomenon which may disappear with the restoration of equilibrium. Or such conflicts may produce a chronic state of tension during which an allergen or a purely emotional factor may be responsible for a sudden recurrence or exacerbation of the dermatosis. The autonomic nervous system is the final common path through which the two interacting factors, the allergic and the functional, become effective. It has been pointed out by Wittkower¹² that allergic and functional disorders have in common an overreaction to stimulation, in both the cause is harmless for the healthy person. The reactions produced by a trivial happening in the emotionally tense person and by the allergen in the allergic patient are of the same character. Thus emotional influences can in many ways favor the creation of allergic states and the elicitation of allergic reactions.

A similar interaction of factors this time an allergic reaction to an infectious agent and a functional element, may be causative in lupus erythematosus. Moreover, it may safely be assumed that the dermatoses included in the foregoing list for which the cause is still undetermined but in which a functional element is so often apparent are due to complex interacting factors, not all of which are known so far. This concept of multiple causation and interrelations is most important.

It seems that the predisposition to functional disorder like that to allergic response is constitutional. This diathesis is expressed by a tendency toward excitability and an exaggerated capacity for response to stimuli. Becker has assumed the presence of an inherited protoplasmic instability in patients with such a constitutional background, and psychiatrists have suggested that they have exaggerated hypothalamic responses.¹³ A great deal of systematic investigative work remains to be done. For practical purposes, however, it is sufficient to recognize the presence of functional factors and to know how to deal with them.

PERSONALITY DIFFICULTIES

The basic feature of the personality of the patient with such a diathesis, regardless of age, sex, education or social stratum, is emotional instability. Limitation of space makes it necessary to confine myself to a sketch of the traits commonly encountered in adult

13 Campbell Douglas Gordon. Personal communication to the author.

patients, the personality of the similarly affected child will be omitted from this discussion. Though naturally the group of patients with dermatoses in which functional factors play a role encompasses a large variety of personalities, there are two common varieties of personality patterns.

The patient with the first variety is best exemplified by the obviously tense, "high pressure" type of business man. Such a patient, who is usually overly ambitious and energetic, is inclined to assume unnecessary burdens and to take his responsibilities too seriously. He is active, brisk, persistent and exacting. His intelligence is often above average and frequently he is a perfectionist. His inner instability may be masked by outward calm. Needless to say, such patients are not always men and are not always engaged in business; patients of this type are frequently encountered among government officials and petty officers.

The patient with the second variety of personality, who is more likely to be a woman, often has conscious feelings of insecurity and inferiority. She is inclined to worry unduly and to evaluate incorrectly the essential factors in her life, particularly in the sexual sphere. She is emotionally hypersensitive, easily discouraged and extremely sensitive to criticism. Her personal maladjustment is expressed by shyness and an attitude of detachment and self absorption. Her inner disequilibrium makes social contacts difficult.

Information is often obtained concerning the presence of functional disorders of other organ systems either in the patient or in one of his relatives. Thus a history of functional disturbances of the gastrointestinal system, migraine type of headache, low backache or vasomotor rhinitis aids in establishing the pattern to which the constitutional background conforms. The family history is an important source of information. Excessive nervous tension and instability and allergic disorders are frequently present among the blood relatives, and sometimes—especially in cases of neurodermatitis—the occurrences of such abnormalities in several generations can be ascertained.

THERAPEUTIC MANAGEMENT

In approaching the problem of functional disease, the physician must call on his store of patience, sympathy and tact. Once the suspicion is aroused that the patient's disorder may have a functional basis, every effort should be expended to gain his confidence so that the extent of the nervous disturbance may be determined. Treatment of a full blown neurosis or psychosis is distinctly the province of the psychiatrist who alone has had the specific training and experience necessary to enable him to assume full responsibility for the patient with severe mental disease. Consequently common sense and discrimination must be exercised in deciding which patients must be referred directly to the psychiatrist and which ones will be suitable subjects for the relatively shallow psychotherapy which the practicing physician can administer along with his treatment of the cutaneous disorder. Fortunately the majority of patients with functional dermatoses have only mild emotional disturbances, which can be alleviated by the understanding and interested physician. Therapy of such disorders is not difficult, but not all physicians have the attributes which are essential for carrying it out successfully.

Intelligent sympathy and understanding are the two prime requirements without which no physician can hope to carry out successful psychotherapy. A func-

tional disease is a true disease, its symptoms are very real to the patient, and adopting the attitude that he is "not really sick" will vitiate any attempts to get at the underlying emotional problems. A sympathetic understanding implies not a "hand holding" point of view but a realization that the patient needs assistance in solving his difficulties.

There are two types of physicians who, in spite of interest and sympathy, are unsuited for handling the emotional problems of patients with functional disease. The first is the type of physician whose experience is so limited that he is frequently faced with patients whose personalities, background and life situations he is incapable of understanding. He is likely to blunder in trying to reduce a complex emotional pattern to his own simple formula without taking sufficient cognizance of factors which, though strange to him, are of great importance to the patient's welfare. One must remember that "normal" covers a wide range in sexual, social and moral as well as physical spheres.

The second type is the physician who has unsolved problems of his own which are likely to bias his approach and to distort his therapeutic attempts. He will often do positive damage either by reinforcing abnormal trends in the patient which parallel the course of his own difficulties or by failing to recognize important factors because they play a role in his own problems.

However, the physician who is equipped with the necessary attributes and a good measure of common sense can greatly aid the patient in unraveling his emotional problems. The "high pressure" type of patient needs advice on how to restore balance to the conduct of his life. The sensitive, easily depressed person needs encouragement and help in gaining a perspective toward his needs and interests. In addition to lending a sympathetic ear to the patient's difficulties and giving advice, the physician can utilize several practical means to reinforce the effects of therapy. For instance, he can often help to eliminate causes of friction by interviewing marital partners or relatives and by suggesting alterations in living arrangement. He can assist in outlining a regimen which will provide for adequate rest, including daily naps and regular sleeping hours. He can discourage excessive social striving. He can insist on a daily balance between work and play and point out the value of restful vacations. The relaxing beneficial effects of daily sunbaths have been well established. The acquisition of an ultraviolet lamp to provide artificial sunshine during the rainy or foggy months is a warranted investment. Relaxation may also be achieved by regular daily exercises and by taking walks, preferably in the country. Sedation is often a necessary adjunct to the foregoing therapeutic suggestions.

It has been my experience that such simple measures often aid in restoring the functional stability of the nervous system. If they are applied in addition to well established therapeutic methods, the prognosis of dermatoses in the causation of which emotional factors are operative is considerably improved.

CONCLUSION

A common sense evaluation of complicating or underlying emotional abnormalities by an understanding and sympathetic physician can be an important factor in the patient's recovery from a chronic recurrent dermatosis.

1930 Wilshire Boulevard

MULTIPLE SPONTANEOUS IDIOPATHIC SYMMETRICAL FRACTURES

MILKMAN'S SYNDROME

LOUIS EDEIKEN, M.D.

AND

NORMAN G. SCHNEEBERG, M.D.

PHILADELPHIA

In 1930 and in 1934 Milkman¹ reported a case exhibiting a skeletal osteopathy which he considered unique and which he named "multiple spontaneous idiopathic symmetrical fractures." In the succeeding twelve years we were able to find references to only 3 similar cases in the English literature and to 15 cases in the foreign medical literature. Our purpose in this report is to review briefly the literature and to add a twentieth case.

This syndrome is characterized by pain, disturbances of gait and the radiologic appearance of multiple transparent bands or zones often symmetrically located in various portions of the skeleton usually interpreted as representing fractures. Locomotion eventually becomes so impeded as to render the patient bedfast.

REPORT OF CASE

History—Mrs. H. S., aged 34, a native American housewife was admitted to Mount Sinai Hospital on July 16, 1942, complaining of weakness, painful lower extremities and inability to walk. She described difficulty on arising from the supine or sitting position, limitation of motion of the right hip and calf and pain in the left thigh on weight bearing which at the time of admission were so severe as to preclude any attempt at locomotion. A peculiar, hesitant, waddling gait had been noted before complete incapacitation had developed.

Past Medical History—The patient had a normal spontaneous birth at term; her birth weight was about 5 pounds (2.3 Kg.). At the age of 6 weeks an illness developed which required rectal feedings for three weeks and produced considerable loss of weight and poor health for two years. At the age of 7 years a fracture of the right tibia resulted from trauma so mild that an osseous defect must have been present at that time. An infection of this fracture required "bone scraping," suggesting that an osteomyelitis had been present. Her only childhood diseases were measles at 6 years and whooping cough at 9 years of age. Trauma to the right knee at 14 years necessitated another "bone scraping." She was ambulatory shortly after this period and recalls that at 17 years of age she weighed 88 pounds (40 Kg.). Intermittent pains in the right thigh and inability to walk without the aid of canes occurred at 21 years and continued until a remission five years later. In 1938 cramplike pains in the left thigh most severe on arising necessitated another hospitalization when only tenderness to deep palpation in the medial aspect of the left thigh could be elicited on physical examination. Roentgenogram taken at that hospital revealed evidence of an osteomyelitis of the lower end of the right tibia, multiple incomplete fractures through the cortices of both femoral shafts, thinning of the femoral necks, flattening of the femoral heads with erosion of both acetabular cavities and a number of old fractured ribs. She was readmitted a year later for similar complaints and was discharged with the tentative diagnosis of a variant of osteogenesis imperfecta tarda. Her symptoms continued without amelioration finally necessitating her present admission.

Systemic Inquiry—Aside from her main complaints, the patient considered herself in fair health, though weakness and loss of weight occurred after confinement to bed for any appreciable length of time. Her menstrual history was normal. No pregnancies or miscarriages had occurred during her five years of married life.

Family History—No similar illness had appeared in any member of her family. There was no history of any hereditary or familial disease. The mother was living and well, the father died in 1920 of cancer of the throat. Three siblings were living and well.

Physical Examination—On admission the temperature, pulse rate and respiratory rate were normal and the blood pressure was 94 systolic and 60 diastolic. The patient was thin, sallow complexioned and dwarfed. She measured 52½ inches (133 cm.) in height and weighed 58½ pounds (26.6 Kg.). Her head was proportionate to her body; there was no tenderness of the skull. The scleras were white, the fundi were normal, vision was 6/6 and the visual fields were normal. The mouth, pharynx and tongue were normal. Compensation existed for extracted teeth. There was slight submaxillary adenopathy; the thyroid was not palpable. She had atrophic breasts, generally limited expansion and no rib or sternal tenderness. The heart, lungs and abdomen were normal. Pelvic and rectal examinations were negative. Neurologic examination revealed some disuse atrophy of the leg muscles, generally hyperactive tendon reflexes and unsustained ankle clonus. Babinski, Chvostek and Trousseau's signs were not elicited. Skeletal examination of the trunk and limbs showed that they were in normal proportions. There was mild kyphosis and some limitation of spinal flexion. Rotation and lateral bending were demonstrable but no spinal tenderness or settling. There was moderate deep tenderness to palpation over the left midthigh and limitation of abduction and flexion at the left hip. No bowing or gross deformities of the long bones could be demonstrated.

Laboratory Studies—The hemoglobin level was 13.9 to 14.5 Gm. (96 to 100 per cent), red blood cells numbered 4,800,000, white blood cells 6,500 to 7,000 with 50 to 55 per cent segmented cells, 2 per cent nonsegmented cells, 41 to 44 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils and 290,000 platelets.

The urine usually was a pale straw color with a specific gravity of 1.009 to 1.012 and a trace of protein. Sugar showed a faint trace on June 13 and Oct. 5, 1939, was plus 2 on June 17, 1942 and was not present on July 17 and 29, 1942; there was no ketonuria and no appreciable number of red or white cells. Bence Jones protein was not present.

June 16, 1938 the blood sugar was 96 mg. per hundred cubic centimeters, urea 10 mg., calcium 9.6 mg., phosphatase 5.6 Bodanski units, result of the dextrose tolerance test: fasting 75 mg. or sugar, thirty minutes 190 mg., sixty minutes 162 mg. and one hundred and twenty minutes 102 mg.

Oct. 5, 1939 the blood sugar was 87 mg., urea 14 mg., calcium 11.0 mg., basal metabolic rate plus 9 per cent.

July 17, 1942 the blood sugar was 90 mg., urea 15 mg., calcium 9.4 mg., phosphorus 2.0 mg., phosphatase 14.8 units (Kav-Roberts), sedimentation rate 16 mm. in sixty minutes.

August 18 the blood urea was 16 mg., chlorides 520 mg. (plasma).

August 19 the blood calcium was 9.7 mg., phosphorus 2.0 mg., phosphatase 14.1 units (Kav-Roberts).

August 20 the blood cholesterol was 270 mg., cholesterol esters 160, icterus index 8 units, basal metabolic rate plus 8 per cent.

August 24 the blood urea was 17 mg., urea clearance 73 per cent, uric acid 2 mg.

August 28 the Fehling concentration test showed a specific gravity of 1.012, 1.011 and 1.012; a blood galactose tolerance test revealed a peak level of 83 mg.

September 3 the blood calcium was 9.3 mg., phosphorus 2.6 mg., phosphatase 14.2 units (Kav-Roberts), blood sodium 401 mg., potassium 15.1 mg., total blood proteins 7.8 mg., serum albumin 4.3 mg., serum globulin 3.5 mg., dextrose tolerance test: fasting 94 mg. or sugar (urine negative), thirty minutes 180 mg. (urine positive), sixty minutes 190 mg. (urine

moderately positive), one hundred and twenty minutes 100 mg (urine weakly positive), one hundred and eighty minutes 65 mg (urine negative)

September 9 the blood chlorides were 610 mg and the carbon dioxide combining power was 47 volumes per cent

Wassermann, Kahn and Kline reactions of the blood were negative

Results of the calcium balance study, bromsulphalein test and gastric analysis are given in table 1

TABLE 1—Results of Tests

Calcium balance study					
Daily intake of calcium 500 mg orally					
8/1/42—Feces 133 mg	Ca in urine 91 mg	= total 1621 mg Ca			
9/1/42—Feces 221 mg	Ca in urine 91 mg	= total 3111 mg Ca			
9/1/42—Feces 611 mg	Ca in urine 210 mg	= total 668 mg Ca			
9/15/42—Bromsulphalein test		Retention in 0 Minutes			
5 mg per kg		0%			
10 mg per kg		2%			
9/23/42—Gastric analysis					
	Fasting	30 Min	60 Min	90 Min	120 Min
Free acid	0	2	20	20	30
Total acid	15	10	10	15	50

Cystoscopy revealed a grossly normal urinary tract, normal renal function and no pyuria The electrocardiogram was normal

A provisional diagnosis of osteomalacia was entertained Skeletal roentgenograms were then made which revealed changes strikingly similar to those described by Milkman as being characteristic of the Milkman syndrome The films were submitted to Dr Milkman, who confirmed the diagnosis They

was noted at the site of a pseudofracture, the femurs showed bilateral coxa vara and the pelvis was heart shaped There were no areas of rarefaction in the skull or vertebrae, though the latter exhibited decalcification and a diminution in height, a biconcave appearance of the bodies and some scoliosis

The following fractures were noted (1) symmetrical fractures of both clavicles, (2) symmetrical fractures of the avl

Fig 2—Lesion in right tibia

lary borders of both scapulas, (3) right radius and ulna, (4) left ulna, (5) numerous ribs, (6) both femurs (asymmetrical), (7) right tibia and (8) left fifth and right third metatarsal

COMMENT

No standard nomenclature has been adopted to classify this type of skeletal dystrophy Leedham Green - objected to Milkman's awkward title and suggested the term "osteoporosis melolytica" or "osteoporosis meloclastica," which pertained to an elective affinity of the process for the bones of the limbs and emphasized the doubt as to whether the lesions observed by radiologic examination indicated true fractures or merely areas of decalcification These lesions, however, are not limited to any portion of the skeleton, and it is thus doubtful whether such a nomenclature condensation is justifiable Hopf³ proposed the name morbus Milkman or dysbasia osteolytica dolens Since Milkman first described this syndrome, the use of the patronymic title "Milkman's syndrome" is logical until the pathogenesis of this osteopathy is more completely understood

In Milkman's original description of the disease a woman aged 43 complained of lameness of the back pain on stooping over and difficulty on arising from a supine or sitting position of nine years' duration and exhibited an uncertain duck waddle gait, evidence of

3 Hopf, Max Radiol clin 9 74 88 (March) 1940 cited in discussion by Milkman¹⁴

Fig 1—Lesions of forearms

revealed generalized calcium deficiency of the skeleton, small punched out cortical notches and transverse zones of rarefaction traversing part or all of the bone, usually at right angles to the long axis In a number of lesions the surfaces adjacent to the decalcified bands showed a narrow line of condensation, some periosteal proliferation was observed at the edge of the defects In the left scapula the transverse band appeared to be completely filled in with new bone, and two metatarsal pseudofractures were healed In a number of paired bones the lesions were symmetrical A deformity of the right clavicle

loss of weight, muscle atrophy, diminished stature and pain on pressure over the sternum, ribs and femurs. Forty-three multiple transparent bands or pseudo-fractures were noted, many of which were symmetrical. In 1934 Milkman published the postmortem findings of this case, which will be described later.

Michaëlis⁴ published a report of a similar case in 1932 concerning progressive skeletal pain in a German soldier aged 18 serving in World War I. Roentgenograms in 1926 revealed widespread lesions similar to those described by Milkman plus pelvic involvement and a small defect in the skull. Several biopsies obtained from the cranium, shoulder and radius served only to eliminate the diagnosis of myeloma; parathyroid tissue obtained for biopsy appeared normal.

In 1933 Debray and his associates⁵ described a woman aged 51 whose symptoms began ten years previously shortly after a pregnancy and exhibited a cycle of remissions and exacerbations coinciding with sojourns in the country and return to city life. Walking and finally movement of any kind became sufficiently painful to produce complete incapacitation. Symmetrical fissures of many bones were discovered on x-ray examination. A second report in 1940,⁶ which probably was a further description of the same case, described a functional cure and substantial skeletal recalcification on

In 1936 Duval described the condition of a man aged 35 who complained of leg cramps and difficulty in rising from the recumbent position. Clinical examination revealed only anterolateral symmetrical curvature of the thighs. X-ray examinations of the femurs revealed two symmetrical fractures on the lateral sur-

Fig. 4—Metatarsal lesions

phosphorus (phospho-calcique) and an antisiphilitic arsenical. The patient was followed until 1937 and remained well.

faces apposed by dense bone on the medial surfaces. It was his impression that the pathogenesis was a periosteal dysplasia or osteopsathyrosis. Bone grafts inserted in the fractured areas failed to fill the defects in the femurs completely.

Dall'Acqua⁸ reported the syndrome in a woman aged 43 with a four year history commencing with pain in the lower extremities and progressing to involve many areas. Physical examination revealed only focal areas of deep skeletal tenderness. A great number of transparent striae, as he called them, which were identical with the pseudo-fractures and bands described in previous reports, were noted on x-ray examination.

Guillain, Lereboullet and Auzepy's⁹ patient was a woman aged 55 presenting a typical clinical and x-ray picture of the Milkman syndrome. Five months of treatment with irradiated ergosterol relieved pain completely, restored normal locomotion and resulted in a gain of 7 pounds (3,175 Gm.).

The initial symptoms of a nun aged 58 reported by Garcin, Legrand and Bernard,¹⁰ was difficulty in arising from her knees after prayers. A remarkable improvement followed therapy with parenteral vitamin A and calcium and oral vitamin D. Illustrations included in their report showed progressive repair of the lesions over a period of thirteen months.

The only report in the British literature is that of Leedham-Green and Campbell Golding.¹¹ Their patient, a woman aged 24, had presented typical symptoms for six years.

In 1938 6 cases¹¹ were reported in the literature, all so strikingly similar in clinical and radiologic characteristics that a detailed description would be superfluous. Leriche and Jung's report¹² concerned a woman aged 30, and the authors discussed a similar case that had come to their attention through a Dr. Cassin.

In 1940 Max Hopt³ published reports of 3 cases expressing his agreement with Milkman concerning the specificity of the disease and proposing the nomenclature adjustment discussed previously.

INCIDENCE

The majority of reported cases occurred in middle aged women, although Michaelis first noted the condition in a soldier aged 18, and Leedham-Green's patient was a woman aged 24. In view of the rarity of this entity the distribution of 15 of the 19 cases on the

described postmortem findings of increased vascularity of all the involved osseous tissues which, he believed suggested the presence of a trophic disturbance producing intense focal decalcification.

PATHOLOGY

The postmortem findings in Milkman's case represent the only source for the study of the morbid anatomic changes in the disease. The pathologic visceral changes were not distinctive. The fractures appeared as irregular breaks in the continuity of otherwise normal bone. Sections were submitted to several pathologists, whose diagnoses varied from osteomalacia to osteopsathyrosis. Increased vascularity about the fractures was pointed out by Milkman. Bone biopsies obtained by Michaelis⁴ merely served to rule out the diagnosis of myeloma. The parathyroids of the patient at autopsy and the parathyroid biopsy reported by Michaelis revealed normal glandular tissue.

SYMPTOMS AND SIGNS

The clinical picture almost invariably conformed to a readily recognizable pattern. The onset was insidious, with pain developing either simultaneously in several portions of the skeleton or progressively involving many bony parts. Pain in the lower extremities and lower part of the back, cramplike in nature or resembling lumbago, was aggravated by motion, walking or excessive fatigue. Difficulty on arising from a supine sitting or kneeling position was a frequently described early complaint. The gait became awkward and hesitant and resembled a duck waddle. Locomotion soon was impossible without the aid of canes or crutches, and eventually most patients became bedridden invalids. The duration of symptoms when the patient was first seen by the physician who recognized the syndrome usually was four to five years, interspersed with many episodes of remissions and exacerbations. The general health was preserved except for loss of weight and weakness in patients confined to bed for prolonged periods of time.

Physical examination revealed little beyond focal areas of skeletal tenderness, often not corresponding exactly to the roentgenologic location of the lesions. None of the usual signs of fracture such as fragment mobility, pseudoparalysis or crepitus existed.

LABORATORY STUDIES

The laboratory is of no help in establishing or eliminating the diagnosis. Some of the findings recorded in various case reports are included in table 2.

The blood calcium may be normal or elevated and the phosphorus low, normal or elevated, the phosphatase may be normal but is usually high. The degree of calciuria is inconstant. Important information concerning calcium-phosphorus metabolism will be forthcoming when more calcium balance studies are reported. One patient was in normal balance,² whereas our patient exhibited negative balance. Repetition of our balance studies when the calcium was administered intravenously failed because of technical difficulties. The basal metabolic rate was normal in 4 cases, plus 22 per cent in 1 and plus 41 per cent in another. Milkman's patient and ours exhibited occasional glycosuria. A dextrose tolerance test performed on our patient revealed a slightly elevated dextrose peak and glycosuria in 1.00 urine specimens. Several fasting blood sugars have always been low normal.

FIG. 5.—Lesions in clavicles, axillary border of both scapulas and ribs.

European continent probably is not a significant finding but may represent unfamiliarity with this syndrome among American and British physicians.

ETIOLOGY

Any discussion of the cause of this unusual condition must remain speculative. There has been no evidence to indict nutritional deficiency, parathyroid dysfunction, endocrinopathies or trauma as the cause of the skeletal striae. Camp and McCullough's¹³ theory that the occurrence of all such lesions may be ascribed to the action of conditions which impose stress and strain on bones seems unlikely to us in view of the absence of any objective demonstration of strain in our case or the cases reported in the literature and the peculiar location of many of the transparent zones (i.e. axillary border of scapula, pubic ramus). X-RAY APPEARANCES

The diagnosis must necessarily be made by the roentgenologist. Focal osteoporotic areas progress to form translucent bands, zones or striae of intense local decalcification which appear to spread across the bone or around its circumference, varying in size from several millimeters to a centimeter or more. Eventually a complete transverse solution of bone continuity resembling a fracture may be produced. The bone edges are usually irregular. The bone above and below this transparent zone may appear relatively normal or may exhibit evidence of deficient calcium content. Involvement of paired bones may be exactly symmetrical, though this is not necessarily so. Early there is no osseous deformity produced but in cases followed for protracted periods certain changes have been described. Milkman¹⁴ reported separation, displacement and overlapping, Milkman¹⁴ and Debray¹⁵ noted settling of the vertebral column, dall'Acqua⁵ described a heart shaped pelvis which was present in our case, Michaëlis⁴ and Debray¹⁵ described coxa vara, which was present in our case, Milkman¹⁴ also described rib and ulnar angulation, unilateral clavicular angulation was present in our case. Though Milkman believed that the disease

TABLE 2—Findings in Various Cases

Author	Calcium Mg per 100 Cc of	Phos- phorus Mg per 100 Cc of	Phos- phate	Calcemia Mg per 24 Hrs	Calcium Balance
	Blood	Blood			
Milkman	10-15	2-6 S		400	
Michaëlis	11-13.7	1-6			
Debray	10-11.4	6-7		50	
dall'Acqua	8-9.5	10-13	48-6 units		
Guillaum	11-11.3	4 S	3-7 units		
Garcin	10.4		3-5 Bodanski units		
Leedham Green	9.6	2-2.8 S	50 units		Normal
Our case	9.3-11	2-0.2 G	14-14.8 Bodanski units	01-2.0	Negative

was characterized by the absence of callus formation, Guillaum and his associates,⁹ Debray and his group⁷ and Garcin and his associates¹⁰ demonstrated recalcification of the striae and fractures after suitable therapy, and other authors, including ourselves, have noted attempts at callus formation in isolated lesions.

DIAGNOSIS

The diagnostic criteria have been summarized by Leedham-Green and Campbell Golding² and are listed, with modifications, as follows:

- I Symptoms and signs
 - 1 Pain across the lower part of the back
 - 2 Pain in the lower extremities
 - 3 Awkward hesitant duck waddle gait
 - 4 Difficulty in arising
 - 5 Physical examination negative or reveals focal tender areas
- II Radiographic features
 - 1 Circular areas of calcium deficiency or translucent transverse bands or irregular pseudo-fractures
 - 2 Lesions usually symmetrical
 - 3 Little or no callus formation before therapy
 - 4 Osseous deformities noted only late

DIFFERENTIAL DIAGNOSIS

A variety of diagnoses have been confused with this syndrome and probably many cases have gone unrecognized for this reason. Osteomalacia is the most frequent diagnosis entertained in these patients, and it is entirely possible that the syndrome represents a variant or subgroup of the osteomalacias. Females comprise

the majority of the cases in both conditions and multiple fractures are common to both osteomalacia and Milkman's syndrome. At least two thirds of osteomalacic patients are women who have had numerous and frequent pregnancies. Undernutrition as an etiologic factor is frequently observed, and many students of the disease look on it as a form of adult rickets. Early osseous deformities are characteristic of osteomalacia, and adequate therapy almost invariably will produce x-ray evidence of recalcification. The early production of kyphoscoliosis, lordosis and bending of long bones occurs in osteomalacia but has not been noted until the very late stages of Milkman's syndrome.

Fragilitas ossium is characterized by a familial tendency, blue sclerae, bilateral deafness and cortical thinning of long bones with the production of multiple, irregular sharply angulated fractures followed by adequate callus formation often exhibiting a series of annular rings of callus. Fractures in such patients who live beyond adolescence are rare.

Osteitis fibrosa cystica presents x-ray evidence of bone cysts. The high blood calcium, low phosphorus, elevated phosphatase and hypercalciuria should establish the diagnosis without difficulty.

Hunger osteopathy, described mainly during and shortly after World War I¹⁴ was considered to represent a form of osteomalacia and may be differentiated from Milkman's syndrome by the presence of dietary deficiencies, early osseous deformities and healing with calcification.

Pathologic fractures may occur in Albers-Schonberg disease (marble bones) and transverse bands have been noted in the shafts of long bones.¹⁶ These fractures heal readily, and the x-ray finding of diffuse osteosclerosis is diagnostic. Pseudo-fractures have been observed in a great variety of unrelated diseases¹³ which should be differentiated from the Milkman syndrome without difficulty. These include rickets, celiac disease, steatorrhea, sprue, hyperthyroidism, osteitis deformans, congenital syphilis, states of overloading bone (march fracture and the like), adrenal pituitary bone dystrophy and severe chronic acidosis or hyperglycemia.

TREATMENT

The aim of therapy has been directed to the production of calcification of the osseous lesions. Phosphorized cod liver oil, viosterol, sunlight and ultraviolet irradiation failed to improve Milkman's patient¹⁴. A functional cure and substantial skeletal recalcification was produced by the use of phospho-calcique and an anti-syphilitic arsenical by Debray.⁶ Bone grafts surgically placed in the symmetrical femoral fractures reported by Duval and Merle d'Aubigne⁷ failed to fill in the osseous defects adequately. The case reported by Guillaum⁹ showed a striking amelioration of symptoms and recalcification of bone lesions by the use of irradiated ergosterol. Garcin's patient¹⁰ improved following a course of therapy with parenteral vitamin A and calcium and oral vitamin D. Leedham-Green's patient² was being treated with a preparation containing vitamins A and D and calcium lactate at the time of their report. Our patient has shown some clinical improvement on a regimen of oral vitamin D (50,000 units daily) and calcium lactate, ultraviolet irradiation of the torso and diathermy to the painful areas. She is now able to walk short distances with the aid of a cane, but her roentgen picture is unchanged.

SUMMARY

1 Nineteen cases of multiple spontaneous idiopathic symmetrical fractures (the Milkman syndrome) have been collected from the literature and a similar case has been added

2 The skeletal osteopathy of this condition is characterized by pain, disturbances of gait and the radiologic appearance of spontaneous multiple symmetrical transparent bands or pseudofractures exhibiting little or no callus formation which progress to render the victim bedfast

3 The disease appears mainly in middle aged women

4 There are no distinctive laboratory findings

5 The etiology and pathogenesis are unknown The syndrome may represent a variant or an atypical form of osteomalacia

6 In the 1 case which came to autopsy increased vascularity about the osseous lesions represented the sole distinctive pathologic change

7 Several reported cures have resulted from treatment with calcium, vitamin D, arsenicals and vitamin A

ADDENDUM—After twenty-five weeks of therapy with 50,000 U S P units of vitamin D orally and 3 Gm of calcium lactate daily our patient has gained 19 pounds (8.6 Kg), is free of pain, is ambulatory, although her bizarre duck waddle gait persists, and is able to earn her living Complete skeletal roentgenograms were repeated on April 5, 1943 and revealed excellent healing of all pseudofractures previously enumerated, no new lesions were noted

A TWENTY EIGHT YEAR FOLLOW UP ON A SPLENECTOMY FOR HEMOLYTIC ANEMIA

PERSISTENCE OF HOWELL JOLLY BODIES

O. H. PERRY PEPPER, M.D., AND J. HAROLD AUSTIN, M.D.
PHILADELPHIA

In 1915 a man aged 40 (J. L.) with severe hemolytic anemia was studied by us in the Hospital of the University of Pennsylvania. His presenting symptoms were weakness, dizziness, dyspnea and edema, which had been increasing for two years. The metabolism studies, before and after splenectomy, which were reported in 1916,¹ revealed that soon after splenectomy there occurred a retention of nitrogen, a decrease in the output of uric acid and iron and a pronounced decrease in the definitely elevated excretion of urobilinogen and urobilin.

On admission in 1915 the patient's blood counts showed a hemoglobin varying from 20 to 26 per cent, a red count between 1,100,000 and 1,700,000 per cubic millimeter, a low white cell count and, in addition, all the morphologic picture which in those days established the diagnosis of pernicious anemia, there were many normoblasts and typical megaloblasts. The coagulation time was normal, as was the hemolytic range in hypotonic salt solution, platelets were approximately 100,000 per cubic millimeter. No Howell-Jolly bodies were seen before operation. Achlorhydria was found.

The physical examination revealed a yellowish pallor and an enlarged spleen. No changes were noted in the tongue and no changes in the nervous system. In the light of our present day knowledge, this case might well not be accepted as one of pernicious anemia, but in 1915 we had little doubt of the correctness of our diagnosis of "pernicious anemia of the hemolytic type." It is true that there is a hemolytic element in most cases of pernicious anemia but seldom, if ever, to this

degree. Some today would undoubtedly term this simply an acquired hemolytic anemia—but such cases are usually more acute. There was no familial history to support a diagnosis of the congenital type.

Transfusions improved the blood count and the patient's general condition sufficiently for splenectomy to be performed successfully. The spleen weighed 340 Gm and showed "chronic diffuse and follicular splenitis, with passive congestion and excessive pigmentation, probably hemosiderin." Following operation there was steady improvement, within ten weeks the hemoglobin had risen to 70 per cent, the red cell count to 3,580,000 and the white cell count to normal. Morphologically the blood picture was normal except for the usual postsplenectomy appearance of Howell-Jolly bodies. All evidences of increased blood destruction disappeared. The patient was without symptoms and in excellent health.

Reports of continued good health and normal blood counts were received for four years and then the patient was lost sight of for twenty-four years. On March 25, 1943, just three days short of twenty-eight years since his first admission, the patient stopped in to report. He is now 68 years of age and has been in excellent health ever since his operation except for a "touch of diabetes easily controlled by diet" and a little lumbago. His appearance was that of an elderly man in peculiarly good physical condition. His blood count was normal with a hemoglobin of 99 per cent. The stained blood spread revealed healthy erythrocytes, a normal number of white cells and platelets and a normal differential white count. A small number of Howell-Jolly bodies were present.

Survival for twenty-eight years after splenectomy for hemolytic anemia is by no means unknown, in fact, Dawson² refers to a patient, the first ever to be splenectomized for hemolytic anemia, who survived the operation for forty-five years. On the other hand, it is probable that the present report of the finding of Howell-Jolly bodies twenty-eight years after splenectomy is unique. Most of the reported series of cases followed up years after splenectomy have been recorded from the surgical point of view, and, unfortunately, not one has been found in which any observation on Howell-Jolly bodies has been mentioned (Diamond,³ Pemberton,⁴ Rousselot,⁵ Eliason and Stevens⁶).

Our case, therefore, may well be the longest reported persistence of these peculiar bodies after splenectomy. First described by Howell⁷ in 1890, later by Jolly,⁸ Schmauch,⁹ Morris¹⁰ and others, these bodies have come to be called Howell-Jolly bodies. Again an eponym reveals our ignorance. Nothing is known as to the origin or significance of these bodies. It is usually assumed that they represent a residual particle of nuclear material remaining after the breakup of the nucleus of the erythroblast. Undoubtedly their staining reactions are those of nuclear material, but the constancy of size, eccentric position in the red cell and the fact that only one is usually found in an erythrocyte seem to argue for their being a definite structure. Also they may be found in nucleated red cells in which the nucleus is still round and unbroken.

The Howell-Jolly body is found in man in small numbers in some cases of pernicious anemia, acute severe secondary anemia, hemolytic icterioanemia, sickle cell anemia and leukemia in most cases of which diseases there is active red cell production going on. In none of these conditions are Howell-Jolly bodies apt to be as numerous as after splenectomy. It is known that they persist after erythropoiesis has returned to normal,

but the reason for their occurrence is not known. Probably identical bodies are found in the erythrocytes of many animals during periods of active blood regeneration and especially after phenylhydrazine or pyridine poisoning.

It may be said that the finding of Howell-Jolly bodies in an otherwise normal blood is a very strong indication of the absence of the spleen. Some day a case should be discovered in which splenic destruction, perhaps by traumatic intracapsular hemorrhage, has taken place. It will be interesting to learn whether Howell-Jolly bodies will appear in such a case just as they do after removal of the spleen. In the present state of our ignorance concerning the functions of the spleen we may conclude that in man, in whom the reservoir function of the spleen is almost negligible, the occurrence of Howell-Jolly bodies is the only evidence commonly demonstrable of a loss of splenic function.

BILATERAL CORTICAL NECROSIS OF THE KIDNEYS FOLLOWING SEVERE BURNS

CLARK E. BROWN, M.D., CHAPEL HILL, N. C., AND
GEORGE L. CRANE, M.D., DURHAM, N. C.

When Duff and Murray¹ collected 71 instances of bilateral cortical necrosis of the kidneys in 1939 they encountered no patient in whom burns had been a predisposing factor. In most deaths from burns pathologic condition of the kidneys has been described as tubular degeneration and intense vascular stasis. Necrotic foci in the kidney presumably from direct action of a toxin, and hemoglobin deposition in the tubules from erythrolysis are also described as evidence of more severe damage.² Evidence of still greater renal involvement of a vascular nature is embodied in the following report of bilateral symmetrical cortical necrosis of the kidneys following extensive cutaneous burns.

REPORT OF CASE

History.—A woman aged 32, a housewife, was admitted to Watts Hospital immediately after suffering severe burns when her nightgown caught on fire. No further history was available except that she had three children, the youngest child 1 year old. Her pregnancies and deliveries were uneventful.

Physical Examination.—On admission the temperature was 99.6 F, the pulse rate 84 and the respiratory rate 20 per minute. The patient was in profound shock but was conscious. The blood pressure was imperceptible. Burns of second and third degree involved the skin over the anterior surface of both thighs, the anterior and right lateral aspect of the abdomen, portions of the chest anteriorly and the inner aspects of the arms, forearms and hands. Burns of this degree comprised about 30 per cent of the total body surface while about them an additional 10 per cent was the site of first degree burns. A detailed physical examination was not carried out because of the obvious nature of the injury and the critical condition of the patient. The extent of the burns on the extremities discouraged the intern from taking numerous blood pressure readings. Her general appearance was one of good nutrition.

Laboratory Examination.—On the day of admission the red blood count was 6,350,000 with 17.5 Gm of hemoglobin per hundred cubic centimeters (101 per cent). The white blood cell count was 3,300 with 87 per cent neutrophils, 11 per cent lymphocytes and 2 per cent monocytes. The hematocrit reading was 61 volumes per cent. The urine contained a trace of albumin. Catheterized urine specimens on the third, fourth and fifth days contained a cloudy to semisolid albumin, were loaded with white blood cells and had from a few to 45 red blood cells per high power field. On one occasion there were a few leukocytic casts. No crystals were found in any specimen. On the fourth hospital day the blood nonprotein nitrogen was

165 mg per hundred cubic centimeters, urea nitrogen 100 mg, urea 214 mg, creatinine 4.2 mg, uric acid 5.7 mg, dextrose 153 mg, chlorides 450 mg and sulfadiazine 20 mg per hundred cubic centimeters. The hematocrit reading at this time was 38 volumes per cent.

Course.—The patient was given 500 cc of blood plasma in the emergency room and another 250 cc about twelve hours later. The burned areas were debrided and sprayed with a 2.5 per cent solution of sulfadiazine in triethanolamine. Throughout the first twenty-four hours the areas were sprayed with the sulfadiazine solution every hour and then every two hours for the next forty-eight hours. On the day of admission she received 6,600 cc of fluid by mouth and 1,400 cc by vein in addition to the plasma. One hour following admission 300 cc of urine was removed by catheter and no more urine was passed that day. She lost approximately 300 cc by emesis. On the second day the fluid intake was 5,200 cc and the urinary output was only 40 cc by urethral catheter. The third day intake was 3,500 cc and the output was 35 cc of urine. The fourth day intake was 3,000 cc and the output was 15 cc. The fifth day intake was 2,300 cc and the output was 35 cc. General treatment consisted of symptomatic use of opiates for pain and various stimulants. On the fourth day a transfusion of 500 cc of citrated blood was given without reaction. The temperature rose to 102 F on the second day, dropped to normal on the third day and then gradually rose again to 101 F on the sixth day. The pulse climbed steadily from 84 beats per minute on admission to 154 on the sixth day. The respirations increased during the fifth and sixth days to 28 per minute. The blood pressure could not be obtained on three attempts during the first day. On the second day the only pressure obtained was 70 mm of mercury systolic and zero diastolic. No further recordings were made, but after the second day the patient did not appear to be in shock and was fully conscious, cooperative and reasonably comfortable. During the ensuing three days it became apparent that she was developing progressive renal insufficiency and on the night of the fifth day she became irrational and semicomatose. On the sixth day respirations became very labored, dark frothy fluid appeared at the nose and mouth and she died.

POSTMORTEM EXAMINATION

The burns appeared as previously described. They were covered by a thick crust which was dry, clean and apparently free of infection. The body was opened with the usual Y incision.

The pleural cavities were normal. The right lung weighed 500 Gm and the left 410 Gm. Each on cut section was moderately congested.

The pericardial cavity was negative. The heart weighed 275 Gm and appeared grossly normal. The aorta was of good elasticity and showed only a few atheromatous plaques in the abdominal portion.

The abdominal cavity was normal. The stomach was much distended with dark fluid and gas. The gastrointestinal tract was congested throughout but was otherwise not remarkable. The liver weighed 1,885 Gm and the cut surface appeared slightly opaque. The gallbladder wall was thin and the bile ducts were patent. The spleen weighed 170 Gm and was moist and dark. The right kidney weighed 180 Gm and the left kidney 175 Gm. The appearance of the two kidneys was similar. The capsule was thin and stripped with ease. The surface was mottled with confluent large and small reddish gray opaque areas. These constituted about one half the surface of the kidney. The intervening tissue was pale grayish pink and glistening. The cut surface showed the same confluent grayish yellow opaque foci with hemorrhagic edges limited to the cortex and columns of Bertini (fig 1). The medulla contained distinct striations. The pelvis of the kidneys were not remarkable and contained no crystals or concretions.

Microscopic Examination.—Sections of the lung revealed pronounced capillary engorgement with dilatation of the arteries and veins. The alveoli contained a few pigment bearing phagocytes.

The heart appeared normal except for capillary engorgement and numerous small areas of interstitial hemorrhage.

From the Department of Laboratories, Watts Hospital, Durham, N. C., and the Department of Pathology, University of North Carolina, Chapel Hill.

Section of the stomach showed engorgement and dilatation of the arteries, veins and capillaries.

Several sections of liver showed only one minute circumscribed area of early necrosis of the hepatic cells with pyknotic nuclei and loss of cell outline. Elsewhere numerous mitoses were observed in many of the liver cells. Some of the large branches of the portal vein were filled with an amorphous material consisting chiefly of fibrin and red blood cells.

Fig. 1—Gross appearance of kidney showing alternating zones of necrosis and hemorrhage limited to the cortex.

The spleen showed severe congestion of the sinusoids. The arteries and veins were dilated and engorged. One large vein contained a thrombus of fibrin, red blood cells and leukocytes. This did not fill the vessel, and free blood was seen in the lumen.

Sections of the kidneys revealed a widespread patchy necrosis involving almost the entire cortex. The necrosis in some areas appeared to be further advanced than in others. There was a thin strip of apparently normal tissue just beneath the capsule. In the most severely affected regions almost complete necrosis of the glomeruli and tubular epithelium with loss of the nuclei and blurring of the cell outlines was the outstanding feature. The structures, however, maintained a shadowy characteristic architecture. Hemorrhages and numerous polymorphonuclear leukocytes were scattered through the parenchyma. Most of the interlobular arteries and the arterioles were altered to an advanced degree. The muscular and elastic fibers of their distended walls were fragmented and opaque and were penetrated by minute hemorrhages. Platelet thrombi frequently filled portions or all of the dilated and sagging arteriolar lumens. These thrombi sometimes could be traced from an afferent arteriole into an engorged or necrosing glomerulus (fig. 2). Glomeruli in involved areas stained poorly, contained thrombi, were sometimes filled with masses of red cells in varying degrees of dissolution or were collapsed from apparent rupture. In regions adjoining the infarcted zones the arterioles and glomeruli were engorged but otherwise normal. The epithelium of the convoluted tubules was swollen, granular and in many places vacuolated. Larger arteries showed no changes similar to those noted in the smaller vessels. In many of them, however, there was thickening and reduplication of the internal elastica and fibrous thickening of the intima, a condition obviously antedating the present injury. Evidence of progressive renal circulatory stasis was adduced from the margination of the cellular elements of the blood. In the veins, partially occluding fibrin thrombi were noted. The collecting tubules were normal and contained no crystals. The picture was one of extensive vascular damage, infarction and tubular nephrosis.

The arteries and capillaries of the pancreas were dilated and packed with red blood cells. There were numerous areas of hemorrhage and fibrous exudate in the interlobular connective tissue.

All the blood vessels of the adrenals were dilated and engorged, and there were several small areas of hemorrhage. Several veins contained nonoccluding fibrin thrombi. Sections of the thyroid and ovary revealed dilated arteries packed with red blood cells.

The bone marrow showed moderate hyperplasia of the myeloid elements and numerous megakaryocytes.

The burned areas of the skin showed complete loss or coagulation of the epidermis with extension in some areas for the full depth of the dermis. The blood vessels throughout this burned area and beneath it were dilated and packed with red blood cells. In none of numerous sections was a leukocytic exudate observed.

COMMENT

Urinary suppression in this patient can be taken to indicate the onset of severe renal vascular alterations, these changes are seen to coincide with the period of deep shock the first forty-eight hours after the burn. In fact Moon⁴ considers that "the congestive, hemorrhagic and edematous visceral appearances after extensive burns are of the same pattern as those found after traumatic shock." This author also notes that massive necrosis of the liver and renal cortex have been observed as unexplained secondary effects of shock. The focal necrosis observed in the upper gastrointestinal tract (e.g., Carling's

Fig. 2—Section showing arteries dilated and their walls necrotic, thrombus in one artery and in an afferent arteriole, glomerulus necrotic.

ulcer) in patients in severe shock have been attributed to arteriolar spasm by Penner and Bernheim.⁵ It is an interesting coincidence that Duff and Cooper implicate spasm of the interlobular arteries and arterioles followed by atony as the etiological mechanism compatible with the majority of cases of bilateral cortical symmetrical necrosis of the kidneys reported in

4 Moon, V. H. Shock, Its Dynamics, Occurrence and Management. Philadelphia: Lea & Febiger, 1942.

5 Penner, Abraham, and Bernheim, Alice C. Acute Necrosis of Esophageal, Gastric and Duodenal Ulcerations, Arch. Path. (Aug.) 1939.

literature. The stimulus for this spasm might be a physiologic compensatory factor against shock acting either directly on the vessel wall (hyperadrenalemia) or via nerve elements or might be a substance elaborated at the burn site. It is however, beyond the scope of 1 case report to decide whether these renal changes developed according to the foregoing explanation or as the result of a direct toxic (necrotizing) action of a burn product on the vessel wall.

The formation of thrombi is probably not the first step in the process although vascular injury from anoxia stasis and the likely increase in circulating platelets and burned tissue products may act to favor this. The process does not appear to be embolic, since well defined thrombi cannot be seen in the engorged vessels at the burn site nor are emboli seen in the lung capillaries. Moon states that the coagulation time of the blood in shock is prolonged and in burns is shortened at first, then lengthened. Zinck⁶ in summarizing the vascular changes in 8 cases of burns emphasizes endothelial damage with fibrin thrombus formation and mentions renal panarteritis.

The use of sulfadiazine sprays in our case deserves some comment. The prompt elevation of the blood level to 20 mg per hundred cubic centimeters after dermal application indicates that burned skin is no barrier to its absorption. It also introduces the possibility that the drug may have caused the anuria, although it is much more likely that the anuria antedated the time when an effective concentration of sulfadiazine was reached. The renal changes described by Hellwig and Reed⁷ in a fatal case of sulfadiazine anuria include advanced tubular damage and the deposition of sulfadiazine crystals in the tubules. Coexistent vascular changes were not noted. Other elements in the therapy of our patient such as plasma blood transfusion without obvious reaction and triethanolamine have not been shown to produce similar renal pathologic condition.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ALSTON E. SMITH, M.D., Secretary

SULFATHIAZOLE (See New and Nonofficial Remedies 1942 p 150)

The following dosage form has been accepted

THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO

Tablets Sulfathiazole 0.5 Gm (77 grains)

PITRESSIN TANNATE IN OIL—A suspension in vegetable oil of a water insoluble tannate of the pressor and diuretic antidiuretic principle of the posterior lobe of the pituitary gland (beta-hypophamine) standardized to contain five pressor units in each cubic centimeter (one unit representing the pressor activity exhibited by 0.5 mg of standard powdered pituitary U. S. P.). It is standardized by the method of Hamilton and Row (*J. Lab. & Clin. Med.* 2:120 [Nov.] 1916).

Actions and Uses—Pitressin tannate in oil is recommended for use where the prolonged action of pitressin is desired particularly for the treatment of patients suffering from diabetes insipidus.

Dosage—From 0.3 to 1 cc (3 to 5 pressor units) intramuscularly or intravenously at intervals of from thirty-six to forty-eight hours.

PARKER DAVIS & COMPANY, DETROIT

Ampoules Pitressin Tannate in Oil 1 cc. Each cubic centimeter contains pitressin tannate equivalent to 5 pressor units in peanut oil suspension.

U. S. patent 1960493 (May 29 1934 expires 1951) U. S. trademark 254307

TREATMENT OF SURFACE BURNS

The treatment of burns is directed toward prevention of shock and care of the surface wound. Probably overemphasis has been placed on surface treatment to the neglect of shock and anoxia. Cope suggests that improvement in results which came with the introduction of tannic acid treatment was probably due to better care of early shock rather than to the ability of tannic acid to fix in situ tissue toxins produced by burns. Cope¹ reports the treatment of 39 patients brought to the emergency ward of the Massachusetts General Hospital from the Coconut Grove night club fire. A trial was given to the method in which treatment of shock and anoxia received first consideration, while treatment of the burned surface was simplified to the point of omission of debridement and cleansing. The treatment of the 39 patients consisted in application to the burned surfaces, without any preliminary débridement or cleansing, of sterile boric acid ointment strips secured in place by pressure bandages. Intravenous administration of plasma was begun as soon as possible, in many instances while the patient was still on the stretcher. Two Gm of sodium sulfadiazine was administered at once through the cannula or the needle already in place for plasma transfusion. The dressings were not changed until the fifth to the tenth day. Debridement was not practiced because it was believed that the intact epidermis over the blebs protects against the entrance of bacteria and because bleb fluid does not become contaminated by virulent organisms harbored in gland crypts. Cleansing was considered undesirable because it does not reduce significantly the number of contaminated organisms present unless vigorous scrubbing is resorted to, in which case viable epithelium is injured. The procedure of débridement and cleansing, it is pointed out, involves increased manipulation of

the patient, prolonged exposure of the wounds and a general anesthetic, all of which are conducive to shock.

Cultures of fluid removed under sterile precautions from blebs twenty-four hours to fourteen days old were taken in the laboratory of Dr. Lyons. In a few instances nonpathogenic saprophytes of normal skin were recovered. It was the clinical impression that the healing beneath the ruptured blebs occurred as rapidly as under any of the other agents commonly recommended for the burned surfaces. Another argument in favor of non-debridement of the burned wound is the availability to the wound of chemotherapeutic agents administered internally. Thus the level of the sulfonamides in the bleb fluid of unruptured vesicles followed closely that of the blood plasma, at least on the first few days. The sulfonamide treatment adequately controlled invasive infection. According to Lyons² there was no evidence in these cases of cellulitis, lymphangitis, lymphadenitis or bacteremia. Superficial burns healed in the usual ten to fourteen day period.

The striking feature of the infection which occurred in all the deep burns was its limitation to the tissue devitalized by the original thermal injury. The treatment appeared sufficient to confine the bacterial infection to the devitalized tissue and to protect the living cells from invasive infection or pronounced local necrosis. The advantage of the treatment is its simplicity. The available personnel in an emergency of this type is freed for the care of shock and anoxia.

THE SHOCK THERAPY OF MENTAL DISEASE

For some time shock therapy has occupied the center of psychiatric interest. It is practiced to greater or lesser extent in three hundred and five hospitals for mental diseases, public and private.¹ Many questions with regard to its therapeutic values under various conditions are still to be answered, in fact, psychiatrists are far from agreement as to its methods, indications and results. Lewis² points out that the facts needed to evaluate shock therapy properly are not yet available in spite of its extensive clinical use. The results published appear to be discordant. The statistics reveal a rather chaotic state of affairs. To quote Lewis, "there is as yet no consensus of the basic value of any of these treatments [insulin, metrazol, electric currents and other shock producers], some authors being very enthusiastic over their results, others being unconvinced."

¹ Lyons, Champ. Problems of Infection and Chemotherapy. Surg. 117: 894 (June) 1943.

¹ Cope, Oliver. The Treatment of the Surface Burns. Ann. Surg. 117: 885 (June) 1943.

of favorable results, and still others expressing frank opinions on the inadequacy and even harmfulness of such procedures."

Lewis, however, does not hesitate to admit that insulin, metrazol and electric shock are all valuable in proper hands when supplemented with systematic psychotherapy and other measures available in psychiatric clinics. The discordant reports on the results of shock therapy seem to be explainable as due, at least in large part to lack of uniform standards in the selection of patients for treatment, in the technic of treatments and in the interpretation of the results. Thus, statistics on the results of insulin treatment of schizophrenia, to be of value for comparative and other purposes, must be based on accurate information as to the form of the disease in each case—there are different forms of this disease—as to the special characteristics of the individual patient and as to the criteria used in recording the results as "recovered," "socially recovered," "improved," "unimproved" and so on. Considerations of this kind apply to other forms of mental disease subjected to shock treatment.

Lewis also admits that the many published reports as well as the survey by Kolb and Vogel¹ on shock practices in three hundred and five mental hospitals and clinics, do indicate approaches toward agreement as to the kind of shock treatment best suited for different types of amenable mental disease. Insulin appears to be the choice for schizophrenia or dementia precox and convulsive methods (metrazol and electric current) for affective disorders and involutional melancholia. The field of usefulness of electrically induced convulsion therapy "a safe and convenient method of treatment in mental diseases," appears to be extending. Selinsky² emphasizes its value in making the patient more accessible to psychotherapy. He states that "there can be no doubt of the empirical fact that electroshock therapy is an important contribution to the art and science of mental healing."

Shock therapy has been, and is, a mighty stimulus to psychiatry. As Lewis says "the whole realm of psychiatry has been vitalized with renewed interest." While no explanation of the fundamental nature of shock reactions can be offered now, has not the time come when their therapeutic actions need to be studied on a well organized, cooperative, national and later perhaps international basis in order that shock therapy may be used to the best advantage in the treatment of mental disease?

Current Comment

VITAMINS AND HUMAN GRAY HAIR

The production of achromotrichia in animals by dietary means and the alleviation of the experimentally produced condition by inclusion in the diet of pantothenic acid or some other vitamin of the B complex led to the hope that similar factors might be effective in restoring the original color to gray hair in man. Some studies have suggested that administration of para-aminobenzoic acid or a preparation containing pantothenic acid is followed by darkening of previously gray hair in man.¹ In view of the widespread publicity given to so-called anti-gray hair factors and of newspaper advertising promoting the sale of calcium pantothenate to persons with gray hair, a recent report by Brandaleone, Main and Steele² is of particular interest. These workers carried out an investigation designed to determine more carefully the degree of change in gray hair to be expected after prolonged administration of calcium pantothenate and para-aminobenzoic acid. Vitamin preparations were administered for eight months to a group of elderly men and women with white or graying hair who were confined to the hospital with chronic diseases such as rheumatoid arthritis, general arteriosclerosis and parkinsonism. Of the group of 19 patients 7 received 100 mg of calcium pantothenate, 200 mg of para-aminobenzoic acid and 50 Gm of brewers' yeast daily, 5 received yeast and para-aminobenzoic acid, and 7 yeast and calcium pantothenate. Three methods for judging change in hair color were used: (1) photographs were taken before, during and at the end of medication, (2) samples of hair were clipped from a given area at the time the pictures were made and (3) all patients were seen by the same two observers at least twice a month and notes taken of any change observed. Photographs were found to be useless, slight changes in distance or lighting made considerable difference in the apparent color of the hair. The subjective opinions were claimed to be more accurate than photographs and less discouraging than hair samples. Several changes were noted in the hair of the treated subjects. The most common was the appearance of a yellow or greenish cast to the gray hair. Growth of scattered wavy black hair also became apparent. In several patients there was thought to be greater luster without change in color. In only 2 patients however was there unequivocal change in color. Both were men with brown hair and the change tended toward a return to the original color. This change became apparent after the drugs (the subjects received both calcium pantothenate and para-aminobenzoic acid) had been administered daily for a period of two to three months and increased slowly in intensity until the experiment was terminated. Whether or not comparable observations will be made when younger people with gray or graying hair are studied remains

¹ Sieve B F. Clinical Achromotrichia. *Science* 94: 257 (Sept. 12) 1941.

to be determined. It is already apparent, however, that much of the publicity concerning anti-gray hair factors has left a distorted impression with regard to the ability of compounds to restore the original color to gray hair in man.

THE QUINACRINE-CALCIUM THERAPY OF TYPHUS

The April 1942 issue of the *Deutsche Militararzt* contained a communication by van Meerendonk¹ concerning his experience with quinacrine therapy in 80 cases of spotted typhus. The effect of this therapy was superior to that which he had observed in a group of 300 cases of typhus treated variably with azosulfamide, aminopyrine neosphenamine and convalescent serum. Under quinacrine therapy a lytic fall in temperature took place in from three to five days, and in typical cases the temperature returned to normal in from eight to ten days. The eruption showed little tendency to spread or to assume a hemorrhagic character. Quinacrine was especially effective for patients past 40 years of age. The author was particularly impressed with the results in 7 cases in which a combination of quinacrine and plasmochin was employed. Occasional failure to reduce the fever within several days was usually due to complicating bronchopneumonia, which was readily controlled by intravenous administration of sulfapyridine. However, in a subsequent report van Meerendonk² stated that his results with quinacrine and plasmochin in a group of 225 cases were rather disappointing; in fact, he has gained the impression that quinacrine therapy aggravated the cerebral symptoms, such as the delirium, the epileptiform attacks and the chorea-like and pseudobulbar paralytic manifestations. All these symptoms suggested a state of tetany. Patients became afebrile under the treatment but died three to four days later with symptoms of cerebral involvement. Postmortem examinations revealed in most cases the usual picture of encephalitis of spotted typhus. Estimation of the blood calcium content of typhus patients revealed values as low as 6 mg per hundred cubic centimeters. Van Meerendonk therefore concluded that calcium deficiency was an important factor in the morbidity of typhus and that there was a definite relationship between the low blood calcium and the lesions of the vascular and capillary systems. The fall in the blood pressure, so characteristic of this disease, is probably likewise dependent on the fall in the blood calcium. Quinacrine-calcium therapy of a group of typhus patients aged between 20 and 40 resulted in a prompt fall in the temperature, limitation of the eruption and maintenance of normal blood pressure. Restlessness and tremors were not observed and there were no fatalities. The author is under the impression that the quinacrine-calcium therapy acts as a specific. The treatment consisted in the administration of one tablet of quinacrine

hydrochloride 0.1 Gm three times daily and of the daily injection of 10 to 20 cc of a 20 per cent solution of calcium gluconate or of a 10 per cent solution of calcium chloride. In severe cases as much as 40 cc of one of these solutions was given daily. The number of cases in this last group is not stated, the communication being in the nature of a preliminary report. No definite opinion, therefore, as to the specificity or, indeed, the effectiveness of this therapy can be ventured until further experiences with it are reported.

PUBLICATIONS OF COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry has just issued new editions of four books, *New and Nonofficial Remedies*, *Epitome of the U. S. Pharmacopoeia and National Formulary*, *Useful Drugs and Reports of the Council*. Each of these is a valuable aid to the physician. *New and Nonofficial Remedies 1943*, an official annual publication of the Council, contains descriptions of proprietary and nonproprietary preparations acceptable under the Council's rules with information concerning composition, actions, indications, dosage and cautionary measures. This volume also sets forth the rules of the Council on which acceptability of products is determined and includes a bibliographic index to unaccepted preparations considered by the Council. The seventh edition of the *Epitome* is designed to include information from the U. S. Pharmacopoeia and National Formulary which may be useful to physicians. It contains a brief discussion of the actions, uses and dosage of each drug in U. S. P. XII and N. F. VII. Items that are considered to be without therapeutic value are commented on adversely in the *Epitome*. *Useful Drugs*, now in its thirteenth edition, was prepared to supply the demand for a selected materia medica. The present volume brings the selection up to date. It is composed of a list of drugs of proved efficacy with a discussion of pharmacologic action, therapeutic uses, dosage and methods of administration. A cross section of a year's work of the Council on Pharmacy and Chemistry is available from the 1942 annual reprint of its reports. Many of the functions of this group are well known, but this book brings out details of some of the more inconspicuous but equally meritorious activities of the Council and supplies a more thorough understanding and new appreciation of the Council's progress and accomplishments. It contains reports originally published in *THE JOURNAL* such as preliminary discussions of new developments in therapeutics and timely articles on the status of recognized agents and reports of omission or rejection of products from *New and Nonofficial Remedies*. It also offers a record of current decisions on matters of Council policy. Each one of the publications of the Council has its own distinct purpose. All have the single aim of developing the standards of medical education and the practice of medicine to their highest levels. With the appearance of these publications the Council again makes a valuable contribution to rational therapeutics.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

MEDICAL OFFICER BAILS OUT AT 40,000 FEET

A parachute jump from 40,200 feet was made by Lieut. Col. William Randolph Lovelace 2d near Ephrata, Wash., on June 24 to test oxygen equipment developed under his supervision for the Office of the Air Surgeon, Army Air Forces. The War Department announced on June 30. It was his first parachute jump.

Colonel Lovelace, 35-year-old chief of the aeromedical laboratory at Wright Field, Dayton, Ohio, bailed out into air registering a temperature of 50 degrees below zero. He landed in a wheat field.

The bail-out equipment consists of a small cylinder containing about twelve minutes' supply of oxygen sewn in the flier's clothing and connected to his mask by a tube. Fliers bailing out of a plane must disconnect their masks from the plane's regular oxygen supply. Since unconsciousness occurs within fifteen seconds without oxygen at 40,000 feet, the bail-out equipment is necessary even to get out of the plane. Colonel Lovelace donned two parachutes and was clad in garments developed

EVACUATION OF WOUNDED AND TRANSPORTATION OF HOSPITALS BY AIRPLANE

The Army Air Forces School of Air Evacuation at Bowman Field, Kentucky, has now been established as a permanent installation. The War Department announced on July 8. This paves the way for expansion of the program for training nurses, enlisted men and flight surgeons for air evacuation duty. About 50,000 men who were disabled by wounds or illness have been transported in air ambulances.

The first class of air evacuation nurses was graduated from the school at Bowman Field on February 18, and three additional classes have since completed the course.

The program planned by Brig. Gen. David N. W. Grant, the Air Surgeon, has proved that all types of wounded men can be carried by air. Aboard each of the airplane ambulances is either a flight surgeon or an army nurse and also one non-commissioned officer of the Medical Department. The Army transports are easily converted from troop planes to flying hospitals and some carry as many as 24 patients.

In New Guinea, 7,000 disabled men were evacuated in one month from Buna across the Owen Stanley Mountains to Port Moresby. Another 7,000 men were flown in as well as a field hospital of 250 beds. A complete 25-bed hospital, including surgical equipment, supplies, beds and medicine, was flown from St. Louis to a base in Alaska in arrangement with the Air Transport Command, Army Air Forces, when fire destroyed a base hospital. In less than six days the hospital was completely installed and in operation.

AWARDED LEGION OF MERIT

The War Department announced on July 9 an award of the Legion of Merit to Brig. Gen. Paul R. Hawley, M. C. U. S. Army, for conspicuously meritorious conduct in the performance of exceptional service. As surgeon of the Special Army Observers Group, London, England, and later as chief surgeon of the European Theater of Operations from September 1941 to June 1942, General Hawley displayed remarkable professional ability, keen judgment and devotion to duty and rendered service of exceptional value to the government by planning all hospitalization and evacuation of United States Army Forces in the United Kingdom and maintaining supervision over the medical situation in the European theater of operations. General Hawley graduated from the University of Indiana and from the University of Cincinnati School of Medicine in 1914 from the Army Medical School in 1917 and received the degree of doctor of public health at Johns Hopkins University in 1923. He was commissioned first lieutenant in the medical corps of the regular army in 1917 and later was on the general staff corps eligible list.

The War Department announced on July 8 that Lieut. Col. John P. Bachman of the Army Medical Department has been awarded the Legion of Merit for exceptionally meritorious service in the Hawaiian Department. Colonel Bachman was cited for having operated continuously on casualties from the beginning of the Japanese attack on Pearl Harbor until 4:30 the next morning and then after only a brief rest resuming his surgical work. Colonel Bachman graduated from the University of Buffalo School of Medicine in 1926 and from the Army Medical School in 1928. Col. Malcolm C. Grow, chief surgeon of the U. S. Army Eighth Air Force in England, has been awarded the Legion of Merit for having added a steel helmet to the flak vest which he developed to protect Ameri-

Col. Walter S. Jensen, M. C. (left), executive officer, Office of the Air Surgeon; Brig. Gen. David N. W. Grant, M. C. (right), air surgeon, Army Air Corps; and Lieut. Col. William Randolph Lovelace 2d, M. C. (center).

at the parachute and clothing laboratory at Wright Field. The parachute on his back would open automatically as he jumped by a device attached to the plane. He wore an emergency parachute on his chest. The blast of air and sudden jerk of the parachute tore the thick outer gloves from both hands and snapped off the thin inner glove on his left hand, leaving it bare in quickly freezing temperature.

The parachute's opening jerk caused him to black out. He was fully revived by the time he reached 8,000 feet and landed down with no injury except the frozen left hand. The present bail-out equipment was found to be highly efficient.

Colonel Lovelace graduated from Washington University, St. Louis, in 1930 and from Harvard Medical School in 1934. He received the degree of master of science in surgery from the University of Minnesota and was a member of the surgical staff of the Mayo Clinic before coming on duty with the Army Air Forces on Feb. 15, 1942. He is president of the Aero Medical Association of the United States and a co-winner of the Collier trophy for research in aviation medicine in 1941. He has engaged in research in high altitude flying since 1936.

can fliers in combat. Colonel Grow graduated from Jefferson Medical College of Philadelphia in 1909, served in the national army during the first world war, and was commissioned in the regular army Medical Corps on July 1, 1920. He is also a graduate of the School of Aviation Medicine.

SPECIALTY TRAINING FOR MILITARY OFFICERS AT COLUMBIA

The War Department, Washington, D. C., has selected Columbia University as one of the universities to present intensive courses in the surgical specialties for the training of army medical and dental officers. The special courses at Columbia University vary from four to twelve weeks, and succeeding courses will be offered at least until Dec. 18, 1943, each course being given to from ten to thirty officers. The courses are in anesthesiology, neurosurgery, plastic surgery, surgery of the extremities and thoracic surgery. For Medical Corps officers only those are selected to enter the special courses in surgery who have had a minimum of one year's surgical residency following an internship or equivalent practical training; officers of the Dental Corps assigned to plastic surgery courses should have had a minimum of two years' training or practical experience in oral surgery. During the past academic year two hundred and forty-two medical and dental officers of the Army were assigned through the Surgeon General's Office, Army Air Forces, Army Ground Forces and the various service commands for training under the auspices of Columbia University College of Physicians and Surgeons.

WOMEN DOCTORS COMMISSIONED

At a ceremony on June 19 at First WAAC Training Center, Fort Des Moines, Iowa, Dr. Eleanor Gutman and Dr. Elizabeth Garber became officers in the Medical Corps of the Army of the United States, Dr. Gutman as a captain and Dr. Garber as a first lieutenant. They are the second and third ranking women in the corps, Major Margaret Craiglill being the first (THE JOURNAL, May 22, p. 236). Serving with the Women's Army Auxiliary Corps at First WAAC Training Center, first in the capacity of contract surgeons and then as Women's Army Auxiliary Corps officers, the women physicians have been associated closely with the WAAC almost since its beginning. The bill allowing women doctors to serve in the Medical Corps of the Army passed Congress in May (THE JOURNAL, May 8).

Captain Gutman is the daughter of Dr. Abraham Gutman of New York. She received her B.A. degree at Smith College and her doctor of medicine degree at Yale University and served an internship and residency in the New Haven Hospital, New Haven, Conn. She maintained a private practice in internal medicine and gynecology in New York for eight years.

Lieutenant Garber is the daughter of Mr. and Mrs. E. C. Garber of Dunkirk, Ind. She received both her B.S. and M.D. degrees from the University of Indiana. She served a two and one-half years' internship and residency in pediatrics in the City Hospital at Indianapolis and then specialized in pediatrics at the University of Chicago for six months and was a resident at the Children's Memorial Hospital in Chicago when appointed a contract surgeon to practice at the Fort Des Moines Post Hospital. Both officers later were commissioned second officers in the WAAC. When the bill passed allowing women to serve officially in the Army Medical Corps, each applied for a commission.

CAPTAIN MILLER A PRISONER OF THE JAPANESE

Capt. Edward S. Miller, M. C., A. U. S., has recently been reported a prisoner of war of the Japanese government in the Philippine Islands. Captain Miller graduated from Emory University School of Medicine, Atlanta, Ga., in 1938, and was stationed at Fort William McKinley in the Philippine Islands when the Japanese attacked and later was on Bataan. His home is in Murphy, N. C.

HONORABLY DISCHARGED

The Westchester (New York) Medical Bulletin for July notes that Dr. Lester Wartels of New Rochelle was recently retired from active service as a captain in the Army Medical Department following a surgical operation and has been appointed assistant city physician to succeed Dr. Raymond Shea, who is on active duty in the Army. The position of assistant city physician is actually held, it is said, by Lieut. Col. Robert Latimer, who is on leave for service with the Army.

As a result of an operation performed last fall, Dr. Frank D. Carroll of Rye has received an honorable discharge from the Army Air Forces, having held a commission as captain in the Medical Corps.

Dr. Hyman Millman of Mohegan Lake was retired from the Army, it is said, effective June 29, after having suffered an injury to his spine in line of duty.

Dr. Jerome Engle of Yonkers, who has been honorably discharged, has returned to private medical practice after two years' service with the Army. He was given a dinner recently by a number of his colleagues in Yonkers.

THE WINTER GENERAL HOSPITAL

The 1,777 bed U. S. Army Winter General Hospital at Topeka, Kan., was dedicated on May 22. Among the speakers at the ceremonies were the governor of the state, Hon. Andrew F. Schoepel, Major Gen. Frederick E. Uhl, commanding general of the Seventh Service Command, Lieut. Col. Waldo B. Farum, chief of the Medical Service of Winter General Hospital, and Major Samuel T. Whitebread of the United States Corps of Engineers, who formally delivered the hospital to the medical department.

The hospital, which is of the one story type in which the units are joined by enclosed runways, has the finest equipment obtainable for the care of the sick and wounded. The standard wards have 33 beds and the combination wards ten private rooms and 16 ward beds. There are four closed wards for patients with mental disturbances. The dining rooms are of the cafeteria style. The hospital has a beautiful chapel and auditorium and an automatic fire alarm and sprinkler equipment in each building in addition to the usual manual fire control system. At present there are three hundred civilian, ten five nurses, thirty medical officers, fifteen medical administrative officers, five dental officers, two sanitary corps officers, two chaplains and others in addition to seven hundred medical detachment men and forty quartermaster soldiers comprising the personnel.

The hospital is named in honor of the late Brig. Gen. Francis Anderson Winter of Louisiana, who served in the first world war as surgeon in the lines of communication in France and later as chief surgeon of our forces in England. His widow was present at the dedication ceremonies.

A plan of naming the important clinics, buildings and streets after distinguished deceased officers of the Army has been followed. There is the Woodward Laboratory, named in honor of Lieut. Col. Joseph J. Woodward (1833-1884) of Pennsylvania, a pioneer in photomicrography and a former President of the American Medical Association; the Fletcher Medical Library, named in honor of Col. Robert Fletcher (1823-1917) of the District of Columbia, first editor of the *Index Medicus*; Eustis Road, named in honor of Surgeon William Eustis (1753-1825) of Massachusetts, who served as a medical officer during the Revolution and became Secretary of War in President Jefferson's cabinet and member of Congress and governor of Massachusetts; Myer Road, named in honor of Brig. Gen. Albert James Myer (1828-1880) of New York, distinguished field surgeon and student of military communication; the founder of the Signal Corps and first chief signal officer of the Army and father of the Weather Bureau, and the William Brown Pharmacy, named in honor of Physician General William Brown (1748-1792) of Virginia, author of the first *Pharmacopeia*.

The commanding officer is Col. John W. Sherwood, medical corps, a native of Maryland, who was commissioned in the Army in 1909 and before coming to the Winter General

Hospital was department surgeon in the Panama Canal Zone. The executive officer is Lieut Col Milford T. Kubin of the Army Medical Department, who formerly lived in McPherson, Kan. The chief of the medical service is Lieut Col Waldo B. Farnum, formerly of New York, of the surgical service. Lieut Col Daniel L. Yancey, formerly of Springfield, Mo., chief of the laboratory service, Major Hugh G. Gridy, formerly of Drexel Hill Pa., chief of the x-ray service, Major Raphael Pomeranz, formerly of Newark, N. J., chief of the dental service, Lieut Col Henry R. Sidenham, formerly of Coleman, Texas, and the hospital surgeon is Major Glenn A. Rogers, formerly of Tahmina, Okla. The following officers are assigned to the various services:

MEDICAL SERVICE

Major Forrest Anderson Van Nuys Calif
Major Sam Phillips Little Rock Ark
Major George Robson San Francisco
Major Nathaniel Uhr New York
Capt Max Berkovsky New York
Capt Henry Gaban Winchester Mass
Capt Max Wagner Sea Gate N. Y.
Capt Meyer G. Miller Wilmington N. C.
Capt Willard T. Peterson Atlantic Iowa
Capt Isadore Schapiro Brooklyn
Capt George Skura Brooklyn
1st Lieut. Thomas G. Ahearn Chicago

SURGICAL SERVICE

Major Charles Alexander Houston Texas
Major Sidney Bernstein Brooklyn
Major Ralph B. Mullen San Diego Calif
Major Matthew Peelen Kalamazoo Mich.
Major Walter A. Reese Middletown Ohio
Capt. Orrin Anderson Clinton Springs N. Y.
Capt William Ellett Appleton City Mo.
Capt. Henry Mosher Dayton Ohio
Capt. Conrad I. Karlsen Traver Minn.
Capt. Joseph Lovering New York

DENTAL SERVICE

Major Claire J. Wilson Haas Kan
Capt Robert E. Brown West View Pa.
1st Lieut Edwin H. Getz Forest Hills Long Island N. Y.
1st Lieut Arthur H. Walden Colorado Springs Colo

DENTAL HYGIENISTS NEEDED FOR ARMY DISPENSARIES

To supply the Army with dental hygienists, the U. S. Civil Service Commission has eliminated the experience requirement for such personnel. Many hygienists are in demand for army hospitals and dispensaries throughout the country, particularly in the West and Southwest. Dental hygienists are under federal civil service regulations and are stationed only within the United States. They receive \$1,970 a year entrance salary including overtime pay. The work week of forty-eight hours includes eight hours of overtime.

Completion of a course in a recognized school of oral hygiene and registration as dental or oral hygienist is all that is necessary to qualify for the positions. There are no age limits and no written tests. Standard application forms must be filed with the United States Civil Service Commission, Washington, D. C. Persons studying oral hygiene may also file receive provisional appointments and enter on duty after completion of their courses and registration. Persons who are willing to work in any part of the country have the greatest chance of receiving appointment within a short time. Applicants who desire information about living conditions in areas where army hospitals and dispensaries are located should on receiving offer of appointment get in touch with the appointing officer for such information. It is possible that vacancies will occur in the Public Health Service and the Veterans Administration. Persons already being utilized to their fullest capacity in war work should not apply. Federal appointments are made in accordance with War Manpower Commission policies and employment stabilization plans. Persons selected for appointment may be required to secure statements of availability but these need not be secured until offer of appointment is received.

Application forms may be obtained at post offices at Civil Service regional offices and at the U. S. Civil Service Commission in Washington, D. C.

REQUEST FOR PATHOLOGIC MATERIAL FOR ARMY MEDICAL MUSEUM

The Committee on Pathology of the Division of Medical Sciences of the National Research Council has requested publication of the following statement:

In view of the need for pathologic material in undergraduate and graduate education, the Committee on Pathology of the National Research Council urges that all who have suitable anatomic specimens forward them to the curator of the Army Medical Museum, Washington, D. C., for correlation and distribution to other central agencies and to teaching institutions. Material from the following is particularly wanted: the malarial diseases, bacillary dysentery, endamebiasis, the schistosomiasis, filariasis, the trypanosomiasis, the relapsing fevers, the leishmaniasis, the rickettsial diseases, yellow fever, cholera, plague and vaws. On application to the curator, arrangements for transportation will be made.

MAJOR MARGARET JANEWAY IN NORTH AFRICA

Dr. Margaret Janeway of New York City was sworn in as a major in the Army Medical Corps on July 1 according to the *New York Times* after she had been discharged as a first lieutenant in the Women's Army Corps. She thus became the first woman doctor in the United States Army in the North African theater of operations.

Dr. Janeway became an Army contract surgeon in 1942 and was assigned to the WAAC. She was commissioned a first lieutenant last December 23 and landed in Africa on January 26. Her grandfather was a surgeon in the Union Army in the Civil War and she left her practice in New York to follow in his footsteps.

RECORD LOW DEATH RATE IN EVACUATION HOSPITALS

The Surgeon General of the Army, Major Gen. Norman T. Kirk, is reported to have said in New York on July 8 that the death rate in the army's evacuation hospitals during the African campaign was the lowest rate of any army at any time and was between 25 and 35 per cent of admissions in comparison with a mortality rate during the last war in such hospitals of 15 per cent. General Kirk ascribed the recent low record to the use of plasma, excellent surgery and sulfonamide drugs. He said that blood plasma given at the front lines saved lives which would have been lost if not available for the treatment of cases in shock, he added that the cream of surgery in America, the middle aged and the younger men who have been teaching have been stationed at evacuation hospitals at the front.

MEDICAL INSPECTORS GRADUATE

Forty officers of the Medical Department, United States Army, were graduated on June 26 from a special one month training course at the Medical Field Service School, Carlisle Barracks, Pennsylvania. They comprised the seventh class of medical inspectors to receive diplomas at this historic 'West Point' of the Medical Department. The duties of medical inspectors are to supervise sanitation and other medical preventive measures in army camps and to make recommendations for the correction of any insanitary conditions. Thirteen of the officers in the class previously attended a basic course at this school. The class was composed of twenty-eight physicians and twelve sanitary engineers.

MISSING IN ACTION

The War Department has listed as missing in action since May 24 Major Jay E. Tremaine of the Medical Department of the Army. Major Tremaine sailed from San Francisco for the Philippines on April 21, 1941 and after a few months' service in Manila was transferred to Fort Pilar, Pettit Barracks, Zamboanga, Mindanao. Major Tremaine graduated from Rush Medical College in 1930. His former home was at Ajo, Ariz.

CIVILIAN DEFENSE

EMERGENCY AMBULANCES FOR CITIES
IN TARGET AREAS

The director of civilian defense, James M. Landis, announced plans on July 12 for the distribution of eight hundred and four stretcher ambulance bodies to various cities in target areas in the United States. These ambulance bodies when mounted on the chassis of used passenger cars to be provided by the city will strengthen the civilian defense measures in American cities. They are made of noncritical materials and designed to be mounted on the rear portion of the chassis of a Chevrolet, Ford or Plymouth four door sedan, models 1939-1941, after the part of the body behind the front seat has been removed. They have been approved by the Army corps of engineers. These ambulances can carry four stretchers or built in racks and in addition an attendant who rides with the patients.

Ambulance bodies will be distributed to selected communities in the exposed areas only after the city has provided the chassis on which to mount them. Mr. Landis pointed out that thousands of idle cars throughout the country are in dead storage for the duration of the war and that cities may acquire the used four door sedans either by purchase or by gift. He suggested painting the name of the patriotic donor on the ambulance door when a chassis is donated for this purpose.

NEW HOSPITAL UNITS OF CIVILIAN
PHYSICIANS FOR EMER-
GENCY SERVICE

Thirty-seven hospitals and medical schools have substantially completed the formation of affiliated hospital units of civilian physicians under the program of the Office of Civilian Defense and the U. S. Public Health Service to provide supplementary staffs for emergency base hospitals and to assist the Army in extemporized hospitals in a serious military emergency, the Medical Division of the Office of Civilian Defense announced, June 22. Fifteen hospitals have completed units since the first list of completed units was announced, April 15. The recent additions are:

Delaware Hospital Wilmington, Del.
Elizabeth General Hospital, Elizabeth, N. J.
Goddard Hospital, Brockton, Mass.
Greenville General Hospital, Greenville, S. C.
Hillman Hospital, Birmingham, Ala.
Macon Hospital, Macon, Ga.
Medical College of Virginia, Richmond
Methodist Hospital, Dallas, Texas
Millard Fillmore Hospital, Buffalo
Mississippi Baptist Hospital, Jackson, Miss.
Mount Sinai Hospital, New York
Queens General Hospital, Jamaica, L. I., N. Y.
Rhode Island Hospital, Providence
Santa Clara County Hospital, San Jose, Calif.
Waterbury Hospital, Waterbury, Conn.

Members of these units receive inactive commissions in the U. S. Public Health Service and will be called to active duty by the Surgeon General only on the recommendation of the chief medical officer of the Office of Civilian Defense.

As a result of the request by the Army for temporary assistance of the Office of Civilian Defense-U. S. Public Health Service affiliated hospital units for emergency service in extemporized army hospitals in the event of military need, invitations to form units have now been extended to institutions in interior states. In the beginning of the program, invitations were limited to hospitals and medical schools in coastal areas. Up to June 15 a total of 251 institutions had been invited by the Surgeon General to form units. Unit directors had been nominated by 161 hospitals, and of this number 105 have taken their oaths for commissions in the U. S. Public Health Service. In addition, applications had been received from 649 members of units, of whom 303 have taken their oaths.

The institutions that are named in the adjoining column have received invitations since the original list of 191 was announced as of April 15.

HOSPITALS AND MEDICAL SCHOOLS INVITED TO
FORM AFFILIATED UNITS AS OF
JUNE 1, 1943

REGION II

New York City New York Polytechnic Hospital

REGION V

Indiana
Protestant Deaconess Hospital, Evansville
St. Joseph Hospital, Fort Wayne
Methodist Hospital, Indianapolis
St. Vincent's Hospital, Indianapolis

Kentucky

Louisville City Hospital, Louisville
St. Joseph Infirmary, Louisville

Ohio

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to the Netherlands Intelligence Service, a copy of Reich's Commissioner Seyss-Inquart's order, by which Dutch physicians, dentists, pharmacists and veterinary surgeons have been frozen in their professions has reached Allied territory. The text of the decree makes it clear that the dropping of titles and the removal of professional diplomas will be punishable by penal servitude or in extreme cases even with death. Those desiring to leave their professions for any reason even practitioners ready to retire because of old age must secure specific permission from the proper official. Until such permission is received they must continue in their professions. Powers previously held by the heads of the Nazi sponsored Physicians Chamber, Dentists Chamber and so on whereby they could authorize members to stop practicing, were abolished under the decree.

According to the Netherlands Intelligence Service lack of materials and the insoluble lubrication problem have caused a gradual collapse of the Dutch transportation system, according to an underground report. Symptoms of deterioration are visible throughout the Netherlands but effective overhauling of railway equipment is impossible. Automobiles have become a rare sight and those which are still moving are using illuminating gas as fuel and some even wood elements.

According to *L'Effort* France of May 10 publicity regarding medical articles will from now on be controlled unless it contains only a mention of the name and of the article's composition, with the makers' or sellers' name and address and commercial or technical information without advertising the character. All other publicity will be submitted to a special committee to be appointed later responsible for the examination of pamphlets, leaflets and all advertising literature generally. Any direct or veiled promise of recovery and any fallacious indication likely to mislead the public is from now on strictly prohibited.

Transocean Bulgaria May 12 reports from Sofia that the Public Health Directorate has concluded an agreement with Germany for the delivery of German drugs in return for Bulgarian medicinal herbs and other raw materials. The first consignment of drugs sent to Bulgaria will be medicaments for use against malaria.

The number of women doctors according to NPD, Germany May 13 is today 40 per cent higher than in 1939. There are 9,246 women doctors as compared with 5,843 in 1939.

SBT reports from Oslo in the *Svenska Dagbladet* May 13 that fourteen medical students from Oslo University, who were conscripted in Hungary at the beginning of May for compulsory labor have now been released to enable them to continue their studies.

Eskilstuna Kuriren May 10 reports that ill health among Norwegians deported to Germany is catastrophic and several deaths have been reported. Epidemics are raging in the Oranienburg concentration camp where the treatment of Norwegian prisoners is beneath criticism.

L'Effort France of April 13 states that owing to the scarcity of certain drugs the Chambre syndicale has decided that chemists are entitled to refuse to deliver drugs to customers. The newspaper does not specify when.

The March 26 issue of the *Deutsche medizinische Wochenschrift* Leipzig contains a description of the chronic poisoning by arsenic of 170 soldiers. The soldiers were serving in an AA battery stationed near a village where in 1919 containers with poison gas from a nearby munitions depot had been buried. The poison is supposed to have leaked into the water supply

which the soldiers used and this is thought to have been responsible for the reported mass poisoning. Most of the men recovered after a short treatment, only a few being still unfit for military duty.

MEDICAL AND PSYCHIATRIC SOCIAL WORK SCHOLARSHIPS

Seventy-five scholarships in medical and psychiatric social work will be made available to eligible candidates between July 1 1943 and July 30 1944 by the American Red Cross. These are a continuation of the program initiated last December. On successful completion of the scholarship training, students will be assigned to positions on Red Cross staffs in military hospitals where the need for qualified personnel has rapidly expanded because of the war. Candidates may designate the school of their choice from a list of social work schools offering an approved course in medical and psychiatric social work. Educational requirements include successful completion of one year of graduate work in an accredited school of social work, and it will be necessary for each applicant to apply directly to the school of his choice to obtain approval for admission. Awards of full tuition and \$65 a month for maintenance will be made according to the individual qualifications of the applicant in order of receipt of the applications by the assistant director of Red Cross Military and Naval Welfare Service, Hospital Service in the four following Red Cross area headquarters: North Atlantic Area 300 Fourth Avenue New York City; Eastern Area 615 North St Asaph Street Alexandria, Va.; Midwestern Area 1709 Washington Avenue St. Louis; Pacific Area Civic Auditorium San Francisco.

RESTRICTION ON STERILIZER EQUIPMENT

A shortage in the supply for defense for private account and for export, has made it necessary for the War Production Board to amend general limitation order L-266 restricting the sale and delivery of sterilizer equipment except as provided in subparagraph 2 of paragraph D of the order. No person shall sell or deliver sterilizer equipment except for the account of (1) the Army or Navy or the United States (2) any agency of the government for delivery to or for the account of the government of any country pursuant to the act of March 11, 1941 (the Lend-Lease Act) (3) any person to whom an export license covering the specific equipment has been issued by the Board of Economic Warfare provided, however that delivery shall not be made to any person holding an export license issued prior to Feb. 24 1943 unless it has been revalidated by the Board of Economic Warfare (4) any other person who has filed form PD-556 pursuant to paragraph (e) of this order and has been authorized by the War Production Board to receive sterilizer equipment and has furnished to his supplier one copy of such form signed in the name of the War Production Board.

RESTRICTIONS ON DELIVERY OF CAFFEINE AND THEOBROMINE

The War Production Board has amended conservation order M-222 to provide that no supplier shall deliver caffeine or theobromine to any person except as specifically authorized or directed in writing by the War Production Board and no person shall accept delivery of caffeine or theobromine which is delivered in violation of this order. However specific authorization in writing of the War Production Board is not required for the (1) delivery of these drugs for medicinal purposes by any supplier to any person for compounding into standard dosage forms (2) delivery of caffeine or theobromine by any person to any other person for compounding into standard dosage forms for medicinal purposes pursuant to toll agreement or (3) delivery by any supplier to any person in any calendar month of not more than 2 pounds of theobromine and not more than 2 pounds of caffeine. These and other amendments to conservation order M-222 were published by the War Production Board Washington D. C. on July 6.

ORGANIZATION SECTION

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

Alabama

Bills Enacted—S 22 has become Governor's No 425 of the Laws of 1943. It requires the state board of health, with the assistance of the committee on cancer control of the Medical Association of the State of Alabama, to formulate a plan for the care and treatment of indigent persons suffering from cancer and to establish and designate standard requirements for the organization, equipment and conduct of cancer units or departments in general or private hospitals or private clinics of the state. The board is also required to formulate and put into effect an educational plan for the purpose of preventing cancer throughout the state, aiding in the early diagnosis of cancer and informing hospitals and cancer patients of the proper treatment. S 64 has become Governor's No 529 of the Laws of 1943. It requires all persons between the ages of 14 and 50 residing or living in the state of Alabama to have their blood examined for syphilis by an approved laboratory test. Any person sick or injured at the time of the official testing, however, may present a certificate from a physician duly licensed in the state of Alabama temporarily exempting him from the test, but it shall be the duty of the physician to secure the necessary specimen when such person is able to have the test made.

Connecticut

Bill Enacted—H 1383 has become chapter 385 of the Laws of 1943. It provides that any graduate of an approved medical school may serve as a resident physician in any state-aided hospital for the duration of the war and for not more than six months thereafter if the written consent and approval of the Connecticut medical examining board has been obtained.

Florida

Bills Enacted—S 5 has become chapter 21841 of the Laws of 1943. It provides for the creation and establishment of a state venereal hospital to be used for the care, treatment and hospitalization of persons afflicted with venereal disease under such rules and regulations as may be prescribed by the board of commissioners of state institutions of the state. S 306 became law without approval on June 14. It provides for the establishment and creation of an institution of higher learning to be known as the University of South Florida, which shall be a state university and shall have as its primary purpose a school of medicine, a school of pharmacy and a school of dentistry. The law further provides that the school of medicine and the school of dentistry shall be first class medical and dental schools and shall be maintained and operated in accordance with the standards of education approved by the American Medical Association and the American Dental Association.

Illinois

Bills Enacted—S 244 was approved, July 10, 1943. It provides for the establishment and maintenance of county and multiple county public health departments. S 525 was approved, July 10, 1943. It amends the medical practice act by providing

that students matriculating or entering on a medical course during the years 1942, 1943 and 1944 may take a course the elapsed time of which is not less than thirty-six months rather than forty months as previously required. The purpose of this proposal is to enable graduates of accelerated medical schools to obtain licensure in Illinois.

Massachusetts

Bills Enacted—S 544 amends the premarital examination law so as to authorize the execution of the required certificate by a physician registered or licensed to practice in any other state of the United States, in addition to Massachusetts practitioners and commissioned medical officers as now provided. H 1655 has become chapter 506 of the Laws of 1943. It authorizes expenses for medical, hospital and other services rendered to aged persons which remain unpaid at the time of such person's commitment to an institution or at the time of such person's death to be paid directly to the person furnishing such service.

Wisconsin

Bills Enacted—S 313 has become chapter 372 of the Laws of 1943. It provides that no person shall practice medicine, surgery or osteopathy or any other system of treating bodily or mental ailments or injuries of human beings under any other Christian or given name or any other surname than that under which he was originally licensed or registered to practice in Wisconsin or any other state. This law does not apply to a change of name resulting from marriage or divorce, however. S 347 has become chapter 375 of the laws of 1943. It creates a new section of the statutes to make uniform the law with relation to administrative procedure and judicial review of various agencies and boards within the state exercising state wide jurisdiction. This would include the board of medical examiners. A 73 has become chapter 484 of the Laws of 1943. It amends the income tax law by authorizing the deduction therefrom of payment for expenses for hospital, nursing, medical, surgical, dental and other healing services and for drugs and medical supplies incurred by the taxpayer on account of sickness or of personal injury to himself or his dependents in excess of \$50 but not more than \$500. A 665 has become chapter 480 of the Laws of 1943. It amends the law relating to the practice of nursing by authorizing a licensed nurse in another state to be granted a certificate in Wisconsin without examination if her credentials of general and professional educational qualifications are equivalent to those required in Wisconsin.

OFFICIAL NOTES

SUMMER HEALTH HINTS

The next three programs for the series of broadcasts on WLS on Thursdays at 2:45 p. m. under the title "Summer Health Hints" will be as follows:

July 29 'Light Summer Meals'
Aug 5 'Picnic Lunches'
Aug 12 'Hiking'

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

Outbreak of Anthrax—An outbreak of anthrax in western Mobile County involved the illness of 2 men and the death of 12 animals, newspapers reported on June 23. It was believed that the men contracted anthrax while removing the hide of an infected animal.

CALIFORNIA

Psychiatrist Wanted—The California State Personnel Board announces an examination for psychiatrist for the California Youth Authority. The position, which provides a monthly salary of \$425, offers opportunity and responsibility for diagnostic and therapeutic work in juvenile delinquency and youth problems. Applications should reach the state personnel board at Sacramento on or before August 16.

Changes in Industrial Hygiene Personnel—Dr. Clifford Kuh has resigned as director of the state bureau of industrial health to join the Permanente Foundation in California according to *Industrial Hygiene*. Dr. Edward E. Dart, director of the division of industrial hygiene in the Los Angeles Department of Health has resigned to become physician in charge of the Dodge Chicago Plant of the Chrysler Corporation, and Yale Rosenfeld, assistant sanitary engineer U. S. Public Health Service, has been named acting director.

COLORADO

Resignations at the University—Dr. Philip Work recently resigned as professor of neurology and head of the department at the University of Colorado School of Medicine, Denver. Dr. Work is now a lieutenant colonel in the Medical Corps of the Army. Dr. Clough T. Burnett has resigned as associate professor of medicine.

CONNECTICUT

State Medical Election—Dr. H. Gildersleeve Jarvis, Hartford, was chosen president-elect of the Connecticut State Medical Society at its meeting in May and Dr. George M. Smith, Pine Orchard, was inducted into the presidency. Dr. Creighton Barker, New Haven, is the secretary. The next annual meeting will be held in Bridgeport in May.

Memorial to Dr. Steiner—A room adjoining the historical library at Yale University, New Haven, will be furnished as a memorial to the late Dr. Walter R. Steiner, Hartford, a specialist in internal medicine, through the generosity of Mr. Elisha H. Cooper, New Britain. The room will be used as a student reading room and will also house Yale medical memorabilia which include items of historical interest given by Dr. Steiner during his lifetime and others which have been added from his collection by his sisters since his death. Dr. Steiner was a classmate of Mr. Cooper in the class of 1892 of Yale.

Promotions at Yale—William U. Gardner, Ph.D., assistant professor of anatomy at Yale University School of Medicine, New Haven, has been appointed professor of anatomy and chairman of the department. He succeeds Edgar Allen, Sc.D., who died on February 5 while on active duty with the U. S. Coastguard Reserve. Dr. Harry S. N. Greene, associate professor of pathology and surgery at Yale, has been named professor of pathology. Cornelius Osgood, Ph.D., associate professor of anthropology and curator of anthropology in the Peabody Museum, has been appointed chairman of the department of anthropology.

ILLINOIS

Parking Problems of Physicians—At a meeting of the Salem city council on June 21 consideration was given to the complaint of Salem physicians that the two hour parking law would cause them serious inconvenience. The physicians requested that parking spaces be reserved for them. The council decided that an exception could not legally be made for physicians but asked the police commissioner and city attorney to study the problem in order to find a practical solution.

CHICAGO

Promotions at Northwestern—Promotions on the faculty of Northwestern University Medical School include Drs. Mark T. Goldstone to professor of obstetrics and gynecology, Garwood C. Richardson to assistant professor of obstetrics, William B. Serbin to assistant professor of obstetrics, George L. Apfelbach to associate professor of bone and joint surgery, Earl O. Latimer to assistant professor of surgery and George K. Yacorzynski, Ph.D., to assistant professor of nervous and mental diseases.

IOWA

Three Cases of Spotted Fever—Three cases of Rocky Mountain spotted fever with one death had been reported to the state health department up to June 22. One patient was a 14 year old boy in Warren County who first complained of illness on May 26. The patient gave no history of tick bite but had removed ticks from a dog and had worked under a tractor in a swampy area several days before taking sick. The other 2 cases were recorded from Ottumwa in Wapello County, one a boy 2 years of age who had onset of disease June 6 and who died June 16. The third patient was the mother of the 2 year old child who had sudden onset on June 11. Members of the household live in a wooded area at the edge of the city. Two small dogs belonging to the family were tick infested. The mother knew of no tick bite but had removed ticks from the child shortly before the illness.

MAINE

State Medical Election—Dr. Raymond V. N. Bliss, Blue Hill, was chosen president-elect of the Maine Medical Association at a business meeting in Augusta on June 20 and Dr. Oscar F. Larson, Machias, was inducted into the presidency. Dr. Frederick R. Carter, South Portland, is secretary-treasurer.

MICHIGAN

Student Loan Fund Created—A scholarship and loan fund amounting to \$4,000 has been established at Wayne University, Detroit, for the use of students in medical technology under a grant from the W. K. Kellogg Foundation. Of the total grant \$2,000 will be used as a loan fund. The other half will be used to furnish scholarships to students in the clinical period. The medical technology curriculum is sponsored jointly by the college of liberal arts and the college of medicine.

Personal—Miss Mary P. Connolly, director of health education for the Detroit Department of Health, is retiring after twenty-five years' service. Dr. Duncan J. McColl, Port Huron, was honored at a dinner, May 25, given by the St. Clair County Medical Society in recognition of his completion of fifty years in the practice of medicine. He was presented with a desk set and a portfolio by members of the society. Dr. Roger V. Walker, Detroit, has been appointed a member of the Michigan Crippled Children's Commission, his term to expire on March 23, 1946.

Special Appropriation for Tuberculosis Care—Effective July 1 the state administrative board will approve increased payments to counties whose hospital bills for care of residents with tuberculosis are out of line with tax incomes. A special \$250,000 appropriation will be available for the purpose in the fiscal year. Benefiting will be counties that are called on to furnish hospital care in excess of forty patient days each year for each \$100,000 assessed valuation. Twenty-five counties qualify for such additional assistance now. Heading the list is Houghton County whose present hospital load is 203 patient days a year per \$100,000 assessed valuation. Also beginning July 1 the state increases its payments to all counties to \$2 per hospital day as against the \$1.50 paid at present, the last legislature having increased the appropriation for the purpose to \$265,000. In no case will the state pay more than \$3.50 for one day's hospital care.

MINNESOTA

Special Unit for Study of Infantile Paralysis—The National Foundation for Infantile Paralysis has approved a five year grant of \$175,000 to the University of Minnesota to set up a special unit to study infantile paralysis. The grant is for the five year period ending June 30, 1948. Building space and basic laboratory facilities are already available at the University of Minnesota. The new unit will be under the general direction of a committee composed of members of the departments of physiology, neuropsychiatry and pediatrics of the medical school. Dr. Maurice B. Visscher, professor and head of the department of physiology will be in charge of administration. An advisory committee will be appointed by

Mr Basil O'Connor, president of the foundation, to assist in directing the committee from time to time. The different departments of the medical school will set up a coordinated medical program which will investigate the mechanics involved in the effects of various treatment procedures, the disturbances in the nervous system which produce the many different kinds of symptoms found in infantile paralysis, the nature of the chemical changes produced in the cells by the infantile paralysis virus and other related problems.

NEW JERSEY

Award to Dr Martland—The Edward J. Ill Award of the Academy of Medicine of Northern New Jersey was presented on May 20 to Dr Harrison S. Martland, Newark, since 1925 chief medical examiner of Essex County. The inscription on the plaque reads "renowned pathologist, dynamic teacher, eminent civic benefactor." Dr Martland graduated at the Columbia University College of Physicians and Surgeons, New York in 1905. He is a past president of the Essex County Anatomical and Pathological Society, which in 1935 established the Harrison S. Martland Lecture in his honor. Dr Martland has also served as director for the Graduate Fortnight of the New York Academy of Medicine. He is professor of forensic medicine of the New York University College of Medicine and in 1936 reorganized the department. For a number of years he has been associate editor of the *American Journal of Surgery*. Speakers at the presentation included Dr Francis Carter Wood, director emeritus of the Institute for Cancer Research, Columbia University, and Dr Edward W. Sprague, president of the Academy of Medicine of Northern New Jersey.

NEW YORK

Fund for Research in Internal Medicine—The University of Rochester ultimately will receive an estimated \$1,784,275 for use as a research fund under the will of Mrs. Bertha H. Buswell, Buffalo. According to *Science*, the will directed that the money be used to establish the "Bertha H. Buswell and Dr. Henry C. Buswell Memorial" for research by the department of internal medicine in the school of medicine. The amount represents the residue of the estate and is subject to a life interest by Mrs. Buswell's brother. The late Dr. Buswell bequeathed \$900,000 for the use of the department of urology in the medical school.

Typhoid Carriers—A total of 437 typhoid carriers, exclusive of those in state institutions, were under supervision in upstate New York at the close of 1942. Thirty new carriers were added to and 25 were removed from the register during the year. Twenty-two were discovered as a result of epidemiologic investigation of sporadic cases of typhoid, 7 by means of release cultures, and 1 was discovered accidentally while hospitalized with a diagnosis of bronchopleural fistula. Of the 25 carriers whose names were removed from the register, 18 died. One was considered cured following cholecystectomy, and 6 others were removed from the register because of change of residence of the carrier to a community outside the jurisdiction of the state health department.

New York City

Industrial Physicians Register—The Long Island College of Medicine announces the creation of a register of more than one hundred and fifty physicians of the metropolitan New York area with experience in industrial medicine and surgery. The register was established as a service to business concerns with health problems or in need of additional medical personnel; it is open for consultation by authorized representatives of business firms who make contact direct with the candidates. The college takes no responsibility beyond making the information available. The file includes names of physicians in all five boroughs of New York, Long Island, Westchester and New Jersey. The register was established after a number of industrial and other types of firms inquired as to whether the college could recommend medical personnel and resulted from the postgraduate course in industrial medicine conducted by the college in November 1942.

Diagnostic Service in Tropical Diseases—On June 18 the laboratory of the city health department in the Meinhard Health Center was moved to enlarged quarters in the Washington Heights-Riverside District Health Center to provide the "tropical diseases diagnostic service of the New York City Health Department." The move was made in anticipation of an increased demand for laboratory service and special information on parasitic and other tropical diseases. For the past eight years the service has been available at the Meinhard Health Center, but it is expected that the service will be more

accessible from all parts of the city in its new location. According to the *Journal of the Medical Society of the County of New York*, physicians, clinics and hospitals may refer specimens or inquiries concerning diagnosis or treatment to the diagnostic service. Information will be furnished by the physician in charge, who is especially trained in tropical medicine about the proper collection and submission of feces, blood and urine and about clinical diagnosis or treatment with regard to cases of a possible parasitic or tropical nature. Reports will be sent directly to the referring physician, clinic or hospital.

Courses in Physical and Occupational Therapy—Columbia University announces special courses to prepare personnel in physical therapy and occupational therapy for immediate and postwar rehabilitation. Both programs are planned to meet the requirements designated by the Council on Medical Education and Hospitals of the American Medical Association and are conducted within the university in close relationship with the College of Physicians and Surgeons, the department of nursing education and the health and physical education of Teachers College. Clinical practice will be given in the Columbia-Presbyterian Medical Center and other hospitals in the New York area. Admission requirements for the nine-month course for physical therapy technicians include two years or sixty semester hours of college work including courses in physics and biology or graduation from an accredited school of nursing or an accredited school of physical education. For the occupational therapy course at least one year of college is required and preferably two years. A certificate of proficiency will be granted by the university following the satisfactory completion of either of these courses. Additional information may be obtained from the physical and occupational therapy office, room 312, School of Business, Columbia University.

NORTH DAKOTA

Dr. Hill Appointed State Health Officer—Dr. Frank I. Hill, Bismarck, who has been acting state health officer for North Dakota for the past eighteen months, has been appointed state health officer by the North Dakota Public Health Advisory Council for a term of four years. He graduated at Jefferson Medical College of Philadelphia in 1930. Dr. Hill also has a degree of master of public health.

PENNSYLVANIA

Isolation Hospital for Venereal Patients—An isolation hospital will be operated by the state department of health at Lancaster for girls and women found infected with a venereal disease. The proposed hospital will be located in a building formerly occupied by the Home for Friendless Children, which has been leased to the state department of health by the county commissioners for one year. The hospital, which will accommodate 75 girls, is expected to be in operation by the end of the summer.

Philadelphia

Signing Health Certificates for Motorists—The Office of Price Administration announced on July 2 that it would report to county medical societies the names of physicians who had signed health certificates which appeared to be unnecessary, according to the *New York Times*. Agents of the OPA assigned to two bridges between Philadelphia and points across the Delaware River said that "up to 50 per cent" of the drivers they stopped had doctors' certificates stating that their holiday trips were necessary for their health. The OPA attorney said that the only excuse for nonbusiness motoring would be a certificate signed by a doctor stating that a person's health would be undermined or his recovery retarded if he could not make a trip and that public transportation would be inadequate. It would be injurious to the patient's health.

Pittsburgh

Harry Meller Dies—Harry B. Meller, head of air pollution investigation at Mellon Institute since 1923 and former chief of the bureau of smoke regulation in the city of Pittsburgh, died on June 27, aged 65. Dr. Meller had been director of the Industrial Hygiene Foundation of America from its founding in 1935 to last September, when he resigned on account of poor health.

SOUTH CAROLINA

Physicians Retire from Teaching Positions—The retirement of Dr. Robert S. Cathcart, head of the department of surgery, Medical College of the State of South Carolina, Charleston, and Dr. John van der Horst, head of the department of physiology, has been announced. Both physicians reached the retirement age and will become professors. Dr. Frederick E. Kredel, professor of surgery, has been

acting head of the department. Dr Cathcart graduated at South Carolina in 1893. He joined the medical college faculty in 1913, when it was reorganized as a state institution as professor of abdominal surgery. He later became head of the department and chief surgeon at Roper Hospital, for which in 1905 he had been instrumental in obtaining a new building. He is a past president of the South Carolina Medical Association, Southern Surgical Association and the Tri-State Medical Association. Dr van de Erve is also pastor of the French Protestant (Huguenot) Church. He graduated at Rush Medical School Chicago in 1911. Before joining the South Carolina faculty in 1919 as professor of physiology he had been associate dean of the Marquette University School of Medicine, Madison Wis., and head of the physiology department at the University of Alabama School of Medicine, University, Ala.

WEST VIRGINIA

Personal—Dr Guy Hurdale, formerly medical director at the Greenbrier Hotel White Sulphur Springs and lately located at Lewisburg has moved to Ogunquit Maine.—Dr Roy R Summers Morgantown who has served as head of the West Virginia University health center for several years has resigned effective August 1. After completing a postgraduate course in surgery, he plans to locate at Charleston.

New Head of Vital Statistics—Dr Martin B Woodward, registrar, state board of health Columbia, S C, has been named as director of the bureau of vital statistics. He succeeds Dr Franklin H Reeder, who is in the military service. Dr Woodward has served as director of a like bureau in the South Carolina Health Department for the past several years. He has been engaged in public health work since 1926.

Dr Offner Named State Health Officer—Dr John E Offner, medical superintendent of the Western State Hospital for the Insane Weston has been appointed state health commissioner by Governor Matthew M Neely for the term ending May 31 1947. He succeeds Dr Clifton F McClintic Charleston who held the office since March 17, 1941 but whose term expired on May 31, 1943. Dr Offner graduated at Maryland Medical College Baltimore in 1904. Dr Offner was located for a number of years at Fairmont, prior to his appointment as superintendent of the Weston Hospital in October 1933.

GENERAL

Quinine Research—Cinchona Products Institute New York, announces the following research projects on quinine and other alkaloids of cinchona. Cornell University Medical College, New York. The action of Cinchona alkaloids on experimental infections, under the direction of Drs Harry Gold and McKee Cattell New York University, a threefold investigation on (a) quantitative study of intestinal absorption and subsequent distribution of the alkaloids between blood brain and body fluids, (b) mode of action on myoneural systems and micro-organisms and (c) action of the alkaloids on isolated enzyme systems, under the direction of Dugald E S Brown Ph.D. New York. Johns Hopkins University School of Medicine Baltimore a study of quinine and malaria in the Upper Mississippi Valley by Dr Erwin H Ackerknecht, under Dr Henry E Sigerist or the Institute of the History of Medicine Battelle Memorial Institute Columbus, Ohio a preliminary study of the industrial uses of Cinchona alkaloids, under the direction of Maynard M Baldwin, Ph.D. and Frank C Croton Ph.D. It was also announced that two research fellowships for graduate workers in this field are now available.

Patents on Manufacture of Vitamin D Held Invalid—The U S Circuit Court of Appeals at San Francisco according to press association reports has declared invalid the patents owned by the University of Wisconsin Alumni Research Foundation governing the manufacturing of vitamin D which are said to have brought to the foundation more than \$7,500,000 in royalties. A licensing system for commercial users of the formula according to briefs in the case had been set up by the foundation and 250 licenses issued all under the control of the foundation. Harry Steenbock, Ph.D. Madison of the university, did the research and obtained the patents on the formula. The ruling of the court or appeals followed an appeal by Vitamin Technologists Inc Los Angeles from a ruling by the federal court at Los Angeles favoring the foundation which had sued for an injunction against and an accounting from the Los Angeles firm on the allegation of infringement of patent. According to the ruling by the court or appeals, all vitamin D patents held by the university and the foundation are invalid and therefore could not be infringed on. It was noted by the court that the patents involved the production of vitamin D for the cure of rickets by means of subjecting

foods to the radiation of ultraviolet rays as produced by a quartz mercury lamp. It was pointed out in the ruling that it had been known for many years that the sun's rays on cut alfalfa hay cured in the field results in an antirachitic food for pigs and that prior to 1923 the effects the rays had on coconut and on milk were known. The decision was written by Federal Judge William Denman. It stated that Dr Steenbock himself had verified these facts with respect to alfalfa and that we thus have the claimed inventor proving that it is from the ultraviolet rays of the sun that the alfalfa acquires its vitamin. That is by the process claimed by him as patentable. Press dispatches also stated that George I Haight LL.D Chicago president of the foundation, has announced that it would appeal the ruling by the San Francisco Court of Appeals.

Tuberculosis Case Registers—As a postwar activity the National Tuberculosis Association plans an intensive campaign to establish central tuberculosis case registers in all centers of the country where health administration is maintained on a sound basis. To this end a manual outlining methods of organizing and maintaining such a central record file has been prepared and will shortly be printed under the direction of Dr Edward X Nikol, a member of the bureau of tuberculosis of the New York State Department of Health Albany. In addition the National Tuberculosis Association is developing a consultant service in connection with the establishment of central registers. Martha Carr Jones statistical assistant in the association has recently been assigned as consultant. The principal objectives of the new central registers will be:

- To record the location and movement of patients at all times.
- To aid in determining the need for the number frequency and location of clinics as well as the need for hospital facilities.
- To indicate deficiencies in the examination and supervision of individual patients and contacts.
- To provide information for the education of physicians nurses health agencies and the public.
- To aid in the appraisal of the tuberculosis problem in a community.
- To aid in the evaluation of the effectiveness of control measures.
- To aid in the planning and organization of suitable health activities.
- To aid in the supervision of public health nurses.
- To provide information to justify requests to appropriating bodies for additional personnel or facilities.

Government Services

Consultation Service in Health Education

The division of industrial hygiene, National Institute of Health, Bethesda, Md, in cooperation with the division of sanitary reports and statistics, is developing a consultant service to stimulate health education programs for industrial workers. Miss Elna I Perkins was appointed recently to the position of associate health education specialist in the division to assume responsibility as liaison in the development of this much needed service.

Physicians Needed for Civilian War Service

The U S Civil Service Commission has liberalized its civil service examination for medical officers in view of the continuing critical shortage of physicians to engage in war work in the civilian branches of the government. There are no written tests and no age limits. Before a definite offer of appointment is made, eligible physicians are cleared through the Procurement and Assignment Service for Physicians Dentists and Veterinarians of the War Manpower Commission.

The twenty optional branches under which doctors may apply range from general practice to aviation medicine. Those appointed will perform professional duties as doctors of medicine in active practice in hospitals in dispensaries or in the field or in rural areas or in bureaus of the government such as the Veterans Administration Civil Aeronautics Administration Public Health Service and Food and Drug Administration. Doctors will also be used in industrial establishments under direction of the War Department. Applicants for all grades must have received the degree of M.D. from an accredited medical school. Applicants for the senior medical officer grade (\$5,228 a year) must have had at least five years of appropriate medical experience for the medical officer grade (\$4,428 a year) three years of experience in addition to a required internship and for the associate medical officer grade (\$3,828) one year of internship. The salaries quoted include overtime pay.

Information and application forms may be obtained at first and second class post offices Civil Service Regional Offices and the commission in Washington, D C.

Salt and Water Requirements in Hot Climates

The war has made important the question of the salt and water requirements of troops in hot countries. The *Army Medical Department Bulletin* states that in order to reduce heat casualties they must be acclimatized and receive the necessary amount of salt and water. Efficient work in hot climates depends on physiologic adaptation—decrease in heat production and increase in sweating. When the body reaches a certain critical temperature, just below 102° F., work becomes inefficient and hyperthermia threatens. Acclimatization is marked by a progressively smaller rise in body temperature for performing a standard piece of work, until those completely acclimatized can work for long periods without rise to the critical level, provided the intake of salt and water is adequate. For troops going to the tropics a month or two of vigorous work in summer heat (about 80° F.) is a good preparation and should be continued during the voyage by exercises.

It has been found experimentally that men properly acclimatized and receiving an ample supply of water require 2 Gm. of salt per hour of work and 0.5 Gm. per hour of rest. Those in sedentary occupations require 12 Gm. daily, those working hard for eight hours daily require 24 Gm. The fresh ration scale in the Middle East, including culinary salt, is 17 to 20 Gm. daily, the canned ration, 22 to 25 Gm. These amounts are sufficient when the water intake does not exceed 2 gallons. Only when this is exceeded is an issue of extra salt necessary.

Adequate water is as important as salt in preventing the effects of heat. Under tropical conditions with a day temperature of 94° F. and a relative humidity of 80 to 85 per cent, the daily excretion of sweat in men on moderate work is 5 to 6 liters. In desert conditions, with a day temperature of 100 to 120° F. and a relative humidity of 25 to 30 per cent, one may excrete as much as 8 liters. For the former a fluid intake of at least 6.5 liters and for the latter up to 9 liters is necessary to maintain the water balance. Some of this intake can be obtained from the water content of food and from the oxidation of foodstuffs, but the daily intake of water should not be allowed to fall below the figures given. For hard work considerably more is required.

It is recommended that men should be encouraged to drink as much water as they want, and preferably more, whenever thirsty, as this increases efficiency and prevents heat symptoms. When extra salt is given it should not be consumed during work but at meals or in rest periods, especially at night. Tablets of 10 grams are supplied and one is to be taken with each pint of water. Taken alone they nauseate.

Labor Party's Plan for a State Medical Service

The labor party has produced a plan for a state medical service similar to that of the Beveridge plan. It urges the establishment of a state medical service and the insurance of the health of all by the entire nation. While admitting that the country's health has substantially improved, it asserts that the physical standard of a great part of the nation remains deplorably low. The annual cost of illness in payments to the sick and in medical services is estimated at \$1,500,000,000. The labor plan is that there should be a central authority to arrange the health services as a whole, including the medical service, subject to the control of Parliament. This authority should be the Ministry of Health, with its accumulated knowledge of national health conditions. Its powers should be extended to cover all the health services, including those now controlled by

other departments, such as the school medical services and the services in factories.

The division of the country into regions, each with its own authority for local government, democratically elected, is recommended. Each regional authority is to appoint its health committee. Within the region there should be a series of divisional hospitals, associated with divisional health centers. The divisional units should be large enough for one fully equipped hospital with specialists of every kind. Experience shows that an economical size for such units is a population of 100,000, which requires a hospital of 1,000 beds.

THE PHYSICIAN'S PART

Changes in the financial status of the physician are advocated. It is argued that the present system of payment is unsatisfactory from the standpoint of the nation, the patient and the physician. The medical profession should be organized as a national full time, salaried and pensionable service. Physicians and nurses should have fixed hours of service, which must be full time, not part time. To the suggestion that some physicians may prefer to retain their private practice and remain outside the scheme, it is replied that the new service should be made so efficient and complete that no patient could desire a better

THE FINANCE

The necessary expenditure should be drawn partly from national taxation and partly from rates payable to the regional authorities. An estimate is given for a comprehensive service for the treatment of the sick (not including cash benefits) of \$700,000,000 annually. This is less than that given in the Beveridge plan, which amounted to \$850,000,000, and it is claimed that the labor plan gives more benefits and greater facilities.

Warning Against Overuse of Warmth in Treatment of Shock

In the *Army Medical Department Bulletin* the War Office has given a warning against overdoing the use of warmth in the treatment of shock. "Keep the patient warm" is an axiom in the treatment of the injured. The harm due to cold was recognized in the last war, when casualties were found to be worse in winter than in summer and the therapeutic value of warmth was readily demonstrated. But one can have too much of a good thing, and apart from accidental burning or unconscious or drowsy patients the enthusiastic application of heat has risks.

After severe injuries the blood volume nearly always diminishes, because fluid has left the blood vessels either from hemorrhage or from oozing into damaged tissues or both. The consequent fall in blood pressure brings into play a vasoconstrictor mechanism which raises pressure by reducing the capacity of the vascular bed. It is not yet certain which parts of the vascular system are affected by this vasoconstriction, but undoubtedly the cutaneous circulation is much diminished. And the capacity of the cutaneous vessels is considerable. Even in a normal person warming may increase the blood content of the skin by as much as a pint. In shock in which the superficial vessels have been constricted and depleted, warming might well bring far more than a pint to the surface, diverting it from its vital functions.

Thus excessive warming may interfere with nature's attempt to restrict its total vascular capacity—the physiologic order, to make a little go a long way. It may accelerate loss of heat from the surface by evaporation and sweating, it may interfere with the metabolism of skin and muscle and thus jeopardize structures whose blood supply is impaired by local injury. It may promote autolysis of damaged tissues and absorption of the products. Experimentally it has been shown that excessive and vigorous heating of injured animals decreases the rate of recovery.

Theory and experiment therefore agree that war casualties should be warmed in a conservative manner, e.g. with blankets and hot water bottles after removal of wet clothes. More potent methods, such as the hot cradle, may be used when the blood volume is being, or has been, restored by transfusion. But the heat should never be so great as to cause sweating and limbs with injured vessels or gangrene should not be warmed at all. As far as the cold or shocked patients is compensatory, it is a symptom which should not be treated energetically unless its basic cause (reduction of blood volume) can be treated at the same time. While warming plus transfusion give excellent and prompt results, warming alone may be carried too far and lead to vasodilatation, circulatory collapse and death.

Publicity Campaign Against Venereal Diseases

The Ministry of Health is continuing the publicity campaign against venereal diseases described in previous letters to THE JOURNAL. The problem has been brought into the open and is freely publicized in broadcasts, newspapers, cinemas, theaters and elsewhere. Posters suitable for both indoor and outdoor display entitled 'Delay Is Dangerous' 'Treatment Must Be Continued and Quack Cures Are Useless' have been sent to the local health authorities by the Central Council for Health Education. The ministry requests these authorities to arrange for a comprehensive and continuing display of the posters in conjunction with a poster giving particulars of local treatment facilities. All health officers have received from the council particulars of the facilities—pamphlets, films and lectures—provided by that body. On application the council will suggest the names of lecturers. In the newspapers advertisements to be continued for at least six months advise readers that information and advice regarding venereal diseases may be obtained from the local health department.

South African Camp for the Wounded

There is in Natal, South Africa, what a woman dietitian working there has described as the largest convalescent depot in the world. It collects empire convalescents from all the hospitals in South Africa and keeps them until they can be returned to their units or sent to England. It can accommodate 4000 patients, and with staffs of all kinds there are nearly 5000 persons living in the camp. The hospital is well built and splendidly equipped and will be turned into a civilian hospital after the war. It is 3500 feet above sea level, in the mist belt, and has a wonderful climate. English fruits grow around it. The depot buildings are mostly made of wattle and daub. Each of the two kitchens has messes which seat 800, and they have a staff of 23 European women and 23 Bulu boys to do the rough work. There is a picture house and a swimming bath. Games—tennis, bowls and football—are provided.

The British Medical Bulletin

A British council has been in existence for some years for the purpose of correcting a belief sedulously propagated by the Nazis that Britain no longer has anything in art, literature or science worthy to be offered to the world. The council has added to its activities a medical bureau. This is in charge of Dr. Howard Jones and prepares abstracts of British medical papers which it circulates throughout the world. These are sent in the language of the receiving country and have been widely reproduced abroad. To supplement this service the council now issues a periodical, the *British Medical Bulletin*, with the object of providing a guide to medical thought in Britain. It consists mainly of summaries of recent papers grouped according to subject. The *Bulletin* is not for general distribution to the medical profession but other journals are invited to reproduce its abstracts. The address of the *Bulletin* is 3 Hanover Street, London, W. 1.

BRAZIL

June 21, 1943

Number of Practicing Physicians in Brazil

According to available information for 1942 there are in this country 18,213 practicing physicians. As the area of the country is 3,287,595 square miles and the population just a little above 43 million, there are therefore an average of about 180 square miles and 2,361 persons to be served by each physician, which corresponds to the rate of 42.35 per hundred thousand of population. But as the density of population varies widely from one state to another (there are twenty states, the Acre Territory and the Federal District), and as the economic development of the several regions of the country is different, the rate of physicians per hundred thousand of population varies also significantly. The highest density occurs in the Federal District (Rio de Janeiro city and its suburbs and rural environs with a total of about 450 square miles), where there are 2,995 physicians, corresponding to a rate of 161 per hundred thousand, or 0.15 square mile per physician. Of course, in the city proper the concentration is much higher, the largest part of these physicians serving in the 60 square miles of the urban area. Next to the Federal District comes the state of São Paulo, the richest section of the country, where there are 6,316 physicians corresponding to the rate of 83.1 per hundred thousand, or about 15 square miles per physician for a state population of 7.6 million. In the city of São Paulo, capital of the state, there are about 1,800 physicians for the population of 1.4 million, scattered over an area of about 40 square miles. In the third, fourth and fifth places stand Rio Grande do Sul, Bahia and Rio de Janeiro, states respectively with 1,785, 1,736 and 772 physicians, or the rates of 51.0, 43.4 and 40.0 per hundred thousand. In the last three places stand the Acre Territory and the states of Piauí and Maranhão, which have respectively 10.96 and 8.3 physicians, corresponding to the rates of 12.0, 9.9 and 7.5 per hundred thousand. The equatorial Amazon basin, where rubber is extracted and where malaria is intensely prevalent, includes the Acre Territory and the states of Pará and Amazonas with the huge aggregate of 1,288,500 square miles and a population of only 1,520,000. In this vast area there are but 241 physicians or a rate of 15.9 per hundred thousand and 5,346 square miles per physician.

Tuberculosis in Southern Brazil

The 1941 annual report of Dr. Bonitacio Costa as commissioner of health for Rio Grande do Sul, the southernmost state of Brazil, gives information concerning the incidence of pulmonary tuberculosis in that state, which has a temperate climate. In Porto Alegre, the largest city of the state, with a population of 275,000, the percentages of cases of active pulmonary tuberculosis have been found with the aid of both clinical and X-ray examinations to be 1.45 among 8,893 state officers and employees, 0.60 among 26,294 commercial clerks and food-handlers, 1.55 among 1,289 pregnant women visiting antepartum clinics, 1.8 among 1,374 school children and 4.20 among 333 workers of the cotton textile industry. In Pelotas (population 105,000) the percentages of active cases of pulmonary tuberculosis have been found to be 0.22 among 2,671 school children, 1.08 among 460 police officers, 0.46 among 4,064 food-handlers, 2.60 among 244 school teachers, 1.61 among 558 pregnant women visiting antepartum clinics and 1.08 among 463 industrial workers of several kinds. In reference to the city of Rio Grande (population 62,000) the report states without giving the absolute numbers the percentages are 0.80 for food-handlers and 2.50 for school children. The Pirquet reaction has given the following percentages of positivity in Porto Alegre: 17.5 among 525 children from 0 to 24 months of age, 41.2 among 342 children from 2 to 6 years of age and 53.7 among 374 children from 7 to 14 years. The examination of

large groups of persons only with the aid of the miniature 35 mm film as suggested by De Abreu, which as a rule furnishes higher percentages, has given 740 per cent of positivity in Rio Grande and 470 per cent among 14,803 persons in Pelotas. In seventy of the eighty-eight counties of the state, the mortality from tuberculosis is considered moderate (below 100 per hundred thousand) but varies between 100 and 300 per hundred thousand in the rest of the state. In Porto Alegre it stays at the average level of 250 per hundred thousand. These figures contrast with those for the northern section of Brazil, where the incidence of tuberculosis is generally higher.

Improvements in the Misericordia Hospital

A new annex to the great old hospital of the Santa Casa de Misericórdia in the downtown section of Rio de Janeiro was opened not long ago. The annex, built with money donated by the Associated Dairies of Brazil under the presidency of Mr. Assis Chateaubriand, has a large surgical unit, sixteen outpatient clinics, a pathologic institute and a physical therapy institute. The surgical unit is under the direction of Dr. Paulo Cesar de Andrade. The outpatient clinics are under the direction of Dr. A. Almeida Silva to give free and low cost medical care. The pathologic institute, under the direction of Dr. Oswaldo Penna, is provided with all the facilities to perform chemical, bacteriologic, parasitologic, anatomopathologic and endocrinologic examinations. The section of necropsies and histopathologic examinations is considered one of the best in South America. The physical therapy institute is equipped with a powerful x-ray apparatus and 500 mg of radium.

The sum donated by the Associated Dairies of Brazil will permit also the granting every year of several fellowships to physicians of the interior of the country to come to Rio de Janeiro to take postgraduate courses in the different specialties of medicine and surgery.

Four New Cases of Quartan Malaria

Dr. Firmino O. Lima of the Malaria Division of the State Department of Health of São Paulo described 4 new typical cases of quartan malaria in patients of that state. Cases of quartan malaria, although relatively rare, are found everywhere, but the prevalence of the disease varies in different regions of the globe depending on favorable influences, perhaps convenient vectors, not yet well recognized. This is particularly true in the case of Brazil, where the quartan type is very rare despite the large importation of the quartan parasite in Italian, Spanish and Portuguese immigrants. Four cases from the state of São Paulo had been previously described by A. Guimarães and M. Cortez, by Prado and Carvalho and by Amaral, Coutinho and Quaglia. The 4 new cases described by Dr. Lima are from the same Itaporanga County where Amaral, Coutinho and Quaglia in 1942 found 2 of the previous cases from the state of São Paulo. For Brazil as a whole, perhaps less than 0.5 per cent of the cases of malaria are of the quartan type.

Prices of Pharmaceutic Preparations

The Division of Prices of the Administration of Economic Mobilization has begun to study the problem of controlling the prices of the pharmaceutic preparations, as they are rapidly rising since a short time ago. All the manufacturers of therapeutic preparations of any kind are obliged to present within thirty days a roster of the respective products, with the description of their characteristics and particulars about their manufacture and distribution. Regarding the products of foreign origin, the authorized representatives of the manufacturers in Brazil are also obliged to file the same information as well as the prices at the country of origin, the existing stocks and other pertinent particulars. The products concerning which information is incomplete or misleading will not be sold until correct information has been filed. The manufacturer who furnishes misleading or untruthful information will be prosecuted according to law.

AUSTRALIA

June 8, 1943

Emergency Rations in the New Guinea Campaign

The lives of many soldiers in the New Guinea campaign have been saved by army emergency rations. The ration tins, 12 ounces in weight, are dropped by planes over isolated areas, many of which are cut off for protracted periods from other sources of supply. The ration consists of a canned meat and vegetable food which increases its bulk fourfold when mixed with water, and a compressed fruit block consisting of apricots, sultanas, currants, sugar and peanuts. Malted milk tablets and tablets of tea, sugar and salt are also included.

Earlier in the Papuan campaign our men were forced to eat unheated food. They could not light a fire because the ground was too damp or because the smoke would have invited attention from enemy snipers. Now they are being supplied with "solidified alcohol" tablets and crown ring cookers. These cookers, which do not rattle and are small enough to fit into mess kits, give off no smoke and are not put out by wind and rain. They are proving of inestimable benefit to men on service in forward areas.

Army Ration on Nutritional Basis

Today the army receives an expertly balanced ration. When Allied soldiers first arrived here they had a separate diet chart from the Australians. The two were soon brought to a common basis by officials of the Council for Scientific and Industrial Research collaborating with the Australian director of army catering (Lieut. Col. Sir Stanton Hicks) and United States Army officials. For the past year the Royal Australian Air Force has been placed on the same catering basis as the army.

The chart for Allied Forces in the Southwest Pacific allows for certain differences in taste—Americans have been found to drink more coffee and Australians more tea, Americans have a wider range of condiments and show a greater preference for ham. It is not always possible to get fresh meat to men in the forward areas, but the preserved lines include canned sausages, dehydrated mutton, bacon and pork packs in addition to the popular meat and vegetable ration. Egg powder, tomato juice and fresh or canned fruits form part of the regular army diet for the forward areas.

Control of Proprietary Medicines

Rigid control of the sale of proprietary medicines has recently been instituted by National Security (Proprietary Medicines) Regulations. The principal objects of the regulations are the prohibition of the manufacture or sale of any medicines which fail to justify their claim, and the compulsory variation of formulas when this is deemed necessary to conserve essential drugs. Advertising of proprietary medicines is virtually prohibited, the only particulars which may be exhibited or published in any form to promote the sale of a proprietary medicine being its trade name, description of the article in not more than ten words, the price, and the name of the manufacturer or distributor. The limitation applies to all written statements concerning proprietary medicine, including advertisements in the press, handbills, window displays and broadcast advertisements. Another section has the effect of prohibiting the employment of travelers or detailists. The definition of "proprietary medicines" given in the regulations is extremely broad and includes any medicines to be held out by advertisement or otherwise in writing, to be efficacious for the prevention, cure or relief of any malady, ailment, infirmity or disease affecting human beings, or for increasing height, strength or reducing weight or increasing personality or reproductive capacity.

Deaths

Lewellys Franklin Barker † Baltimore, emeritus professor of medicine at Johns Hopkins University School of Medicine, former professor of anatomy at the University of Chicago, former Vice President of the American Medical Association and medical leader died on July 13 at Baltimore at the age of 75 after a long illness.

Dr Barker was born in Norwich, Ontario, Canada, on Sept 16 1867. He studied at the University of Toronto and the Universities of Leipzig Munich and Berlin. After work in anatomy and pathology in Johns Hopkins from 1894 to 1899 Dr Barker became associate professor of anatomy at the University of Chicago, returning to Johns Hopkins for a year in pathology and then became professor and head of the department of anatomy at Rush Medical College, Chicago 1900-1905. Dr Barker was professor of medicine at the Johns Hopkins University and chief physician at the Johns Hopkins Hospital from 1905 to 1913. He then became emeritus professor of medicine at Johns Hopkins University and visiting physician to the Johns Hopkins Hospital.

A long and eminent career as an investigator and clinician resulted in many contributions to the medical literature. Dr Barker's early books were principally in the field of anatomy and included a book on the nervous system published in 1899, a translation of Spalteholz's Hand Atlas of Human Anatomy in 1900 and a Laboratory Manual of Human Anatomy in 1904. In 1896 Dr Barker described a unique case of circumscribed unilateral and elective sensory paralysis analogous in its bearings to the observations of Head. In 1909 with Hanes he described the eye signs in chronic nephritis. With Sladen he made interesting clinical and pharmacologic studies of the autonomic nervous system. He published an exhaustive treatise on clinical diagnosis in 1916. In more recent years he has been the author of several popular works on medical subjects. With N B Cole he wrote a book for the public on blood pressure in 1924. His book *The Young Man and Medicine* was written primarily for medical studies. A monograph on psychotherapy appeared in 1940. Dr Barker's autobiography *Live Long and Be Happy* Time and the Physician appeared in 1942.

The recipient of many honorary degrees including the honorary MD from the University of Toronto and the LL.D. by Queen's University at Kingston Ontario and McGill University at Montreal. Dr Barker was also much in demand as a special lecturer. His lectures included the Beaumont Lectures of Wayne County Medical Society Detroit 1935 the annual Alpha Omega Alpha lecture at Jefferson Medical College in 1932 and the first M L Rhein Memorial Lecture of the First District Dental Society of the State of New York in 1933.

Dr Barker was First Vice President of the American Medical Association 1916 to 1917 chairman of the Section on the Practice of Medicine 1921 to 1922 and member of the House of Delegates in 1909. He has been president of the Association of American Physicians the American Neurological Association the Southern Medical Association the Association for Study of Internal Secretions and was one of the vice presidents of the Pan American Medical Association in 1933. He has been in addition an active or honorary member of many other medical societies in this and other countries.

Dr Barker was a man of strong personality whose interests extended beyond pure medical science into all the aspects of medical life and his community. Only a man of tremendous energy as well as ability could have accomplished so much.

Charles Francis Gormly † Providence R I Tufts College Medical School, Boston, 1909, immediate past president, in 1941 vice president and chairman of the committee on industrial health of the Rhode Island Medical Society, president of the Providence Medical Association 1934-1935, at one time chairman of the Rhode Island Board of Examiners in Medicine, fellow of the American College of Physicians member of the American Heart Association and the New England Heart Association specialist certified by the American Board of Internal Medicine, served with the American Expeditionary Forces in France during World War I with the rank of lieutenant colonel lieutenant colonel in the medical reserve corps of the U S Army not on active duty, had been deputy director of the state medical and division of civilian defense as physician in chief at the Rhode Island Hospital organized Evacuation Hospital number 48 now serving abroad, consulting physician to the Butler Charles V Chapin and Providence Lying-In hospitals Providence State Hospital for Mental Diseases and State Infirmary Howard appointed by the governor a member of the advisory council to the state department of health delivered the George W. Gay Lecture on Medical Ethics on the Measure of a Physician's Greatness at the Tufts College Medical School in 1941 at the annual meeting of the state medical society in June 1943 a portrait of him was presented to the society the faculty of the school of nursing of the Rhode Island Hospital established in 1943 the Charles F Gormly Award to be given to the outstanding senior student nurse for the furthering of her professional interest in January 1943 was presented with the medal of award and accompanying citation of the Rhode Island State Dental Society in acknowledgment of many services to the medical and dental professions aged 57 died June 26 of carcinoma of the lung.

James Gibson Logue † Williamsport Pa University of Pennsylvania School of Medicine Philadelphia 1914, specialist certified by the American Board of Pediatrics, Inc member of the American Academy of Pediatrics past president of the Lycoming County Medical Society served as president of the Lycoming County Tuberculosis Society and director of the Lycoming County Crippled Children's Society served in the medical corps of the U S Army during World War I medical director of the South Williamsport Office of Civilian Defense physician to the Pennsylvania Children's Aid Society chief of the pediatric staff and member of the board of managers of the Williamsport Hospital where he died March 25 of aplastic anemia aged 53.

Clifford U Collins † Peoria Ill Physio Medical College of Indiana Indianapolis 1891 Marion-Sims College of Medicine St Louis 1892 member of the House of Delegates of the American Medical Association in 1912 specialist certified by the American Board of Surgery member and formerly vice president of the Western Surgical Association served as president of the Peoria Medical Society one of the members of the advisory board of the state department of health under three different governors organized the Collins Clinic past president of the Peoria Association of Commerce and the Rotary Club aged 75 on the staff of St Francis Hospital where he died May 26.

Arthur Augustus Spoor, Muskegon Mich University of Michigan Department of Medicine and Surgery Ann Arbor, 1901 member of the Michigan State Medical Society state bacteriologist and director of the laboratory of the Michigan State Board of Health from 1914 to 1918 at one time instructor in clinical microscopy and clinical pathology at the Creighton University College of Medicine and pathologist to St Joseph's Hospital Omaha served as pathologist on the staff of the

LEWELLYS FRANKLIN BARKER MD 1867-1943

Mersey Hospital, formerly a member of the city board of health, aged 69, died recently of heart disease at Orizaba, Mexico

William Calvin Kennerdell Berlin, Denver, University of Wooster Medical Department, Cleveland, 1895, member of the Colorado State Medical Society served during the Spanish-American War, member of the staff of St Anthony's Hospital, aged 71, died, April 28

Bertha Breeze Brainard, Jamestown, N D, Rush Medical College, Chicago, 1932, member of the North Dakota State Medical Association, diplomate of the National Board of Medical Examiners, in 1940 appointed in charge of the student health service at Oregon State College, Corvallis, served as health officer of Jamestown, state president of the American Association of University Women, aged 49, died, March 12, in Rochester, Minn, of hepatic abscesses and thrombosis of the portal vein

Louis Cohen, New York, Eclectic Medical College of the City of New York, 1903, formerly on the staff of the New York Hospital, aged 74, died, April 26, of coronary occlusion and arteriosclerosis

Ora O Dawson, Wayne, Okla, University of Oklahoma School of Medicine, Oklahoma City, 1912, member of the Oklahoma State Medical Association, aged 58, on the associate staff of the Wesley Hospital, Oklahoma City, where he died in April of coronary thrombosis

John Walter Dennis, Chicago, Loyola University School of Medicine, Chicago, 1922, formerly health officer of Hamilton County, Tenn, served on the staff of St Elizabeth Hospital, aged 47, died, May 24, of bronchopneumonia

Patrick John Donahoe, Utica, N Y, Albany (N Y) Medical College, 1905, member of the Medical Society of the State of New York, for many years a member and at one time president of the staff of St Elizabeth Hospital, attending physician at St John's Orphan Home, city physician, aged 63, died, May 4, of coronary thrombosis

Frederick Leslie Ecker, Parkers Prairie, Minn, Chicago College of Medicine and Surgery, 1913, aged 68, died, May 3, in Dalton, Ga, of acute coronary thrombosis

Marvin D Fitch, Columbus, Ohio, Medical College of Ohio, Cincinnati, 1897, aged 73, died, April 8

James Thomas Gaines, Crossville, Ala, University of Alabama School of Medicine, 1913, member of the Medical Association of the State of Alabama, president of the De Kalb County Farm Bureau, chairman of the board of trustees of the Crossville High School, aged 54, died, April 17, of coronary thrombosis

Archibald G Henderson Ⓢ Leonardville, Kan, Missouri Medical College, St Louis, 1899, aged 78, died, March 14, of heart disease

John Herbert Johnson, Cambridge, Mass, Harvard Medical School, Boston, 1901, served on the staffs of the McLean Hospital, Waverly, Boston Floating Hospital and the Medford (Mass) Hospital, aged 71, died, April 30, of cardiorenal disease

Christ William Kanne, Faribault, Minn, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, member of the Minnesota State Medical Association, aged 67, died, March 18, at Minneapolis of thrombophlebitis, pulmonary embolism and pulmonary infarction

Albertus L Lloyd, Rapid City, S D, Baltimore Medical College, 1898, served on the staffs of St Joseph's Hospital, Deadwood and St John's Hospital, aged 76, died, March 27, of cerebral hemorrhage

Joseph Charles McFate Ⓢ Meadville, Pa, Western Reserve University Medical Department, Cleveland, 1905, past president of the Crawford County Medical Society, a captain in the medical corps of the U S Army during World War I, served on the staff of the Meadville City Hospital, aged 66, died, April 27, of hypertensive heart disease

Edward George Meter Ⓢ Reading, Pa, Medico-Chirurgical College of Philadelphia, 1897, specialist certified by the American Board of Radiology, Inc, member of the American Roentgen Ray Society and the American College of Radiology, aged 67, chief, radiology department, Reading Hospital, where he died, March 20, of acute coronary occlusion

William Sawyer Newell, Washington, D C, Columbian University Medical Department, Washington, D C, 1895, member of the Medical Society of the District of Columbia, fellow of the American College of Surgeons, ophthalmic surgeon to the Central Dispensary and Emergency Hospital, aged 69, died, June 22, in the Garfield Memorial Hospital

Myron E Osterhout, Cornwall, N Y, New York Homeopathic Medical College and Flower Hospital, New York, 1922, member of the Medical Society of the State of New York, a member of the board of education, on the staff of the Cornwall Hospital, aged 49, died, April 16, of coronary thrombosis

John David Pate, Duncan, Okla (licensed in Oklahoma under the Act of 1908), aged 75, died, April 23

Arthur Colby Robbins Ⓢ Garden Grove, Calif, College of Medical Evangelists, Los Angeles, 1923, aged 50, died, April 21

Reginald W H Rollings, New York, New York Homeopathic Medical College and Flower Hospital, New York, 1910, aged 57, on the staff of the Flower and Fifth Avenue Hospitals, where he died, April 27, of carcinoma of the pancreas

Herman Schlaff Ⓢ Philadelphia, Medico-Chirurgical College of Philadelphia, 1912, served on the staffs of the Jefferson and the Northern Liberties hospitals, aged 61, died, March 6, of acute cardiac dilatation

Walter Henry Scudder, Litchfield, Ohio, Western Reserve University Medical Department, Cleveland, 1891, member of the Ohio State Medical Association, aged 82, died, April 30

William Alexander Sim, Quincy, Ill, Rush Medical College, Chicago, 1902, member of the American Psychiatric Association, served on the staffs of the Veterans Administration Facility in Sheridan, Wyo, and St Cloud, Minn, aged 65, died, April 21, of chronic leukemia

Edwin M Snyder, Roscommon, Mich, Michigan College of Medicine and Surgery, Detroit, 1889, aged 76, died, April 2, of arteriosclerotic heart disease

William Kenney Terribery, Binghamton, N Y, Columbia University College of Physicians and Surgeons, New York, 1907, formerly instructor of physiology at his alma mater, at one time medical examiner for the Mutual Life Insurance Company and associated with the Standard Oil Company at Bayonne, N J, aged 62, died, April 22, in the Binghamton City Hospital of pneumonia and heart disease

James Harvey Van Buren, Elmira, N Y, Albany Medical College, 1905, aged 63, died, April 23, of chronic pulmonary tuberculosis and toxemia

Isidore S Zimmerman Ⓢ Brooklyn, Long Island College Hospital, Brooklyn, 1926, on the staffs of the Israel Zion, Kings County and Jewish hospitals, examiner for the local draft board, aged 41, died, April 21

DIED WHILE IN MILITARY SERVICE

James Morgan Minter Ⓢ Medical Director, Rear Admiral, U S Navy, Washington, D C, University of the South Medical Department, Sewanee, Tenn, 1903, appointed an assistant surgeon in the medical corps of the U S Navy in 1906, became a captain in 1927 and a rear admiral in 1941, served during World War I, formerly sanitary engineer to the republic of Haiti, in command of naval hospitals at Pearl Harbor and San Diego, senior medical officer at the Great Lakes Naval Training Station and at the Naval Academy at Annapolis, held the Victory Medal and the Navy Expeditionary Medal, fellow of the American College of Surgeons, aged 60, died, May 11 in the U S Naval Hospital, Bethesda, Md, of arteriosclerotic coronary heart disease

Theodore Leroy Chamberlin Ⓢ Assistant Surgeon U S Public Health Service, Hartford, Conn, Yale University School of Medicine, New Haven, 1940, diplomate of the National Board of Medical Examiners, commissioned assistant surgeon in the reserve corps of the U S Public Health Service in April 1942, assigned to U S Maritime Training Station, New London, Conn, commissioned assistant surgeon in the regular corps in July 1942 and assigned to U S Marine Hospital, Chicago in January 1943 was assigned to Curtis Bay, Baltimore aboard Coast Guard Cutter *Modoc*, aged 28, was killed May 1, in an airplane accident overseas

Walter Jackson Lackey Ⓢ Fallston, N C University of Virginia Department of Medicine, Charlottesville, 1928, on the staff of the Shelby (N C) Hospital, lieutenant in the medical corps, Army of the United States, stationed at Fort Jackson, S C, aged 36, burned to death May 1, at his home in Columbia, S C when the mattress of his bed caught fire from a lighted cigarette

TYPHUS FEVER IN EUROPE

To the Editor—Since reading your editorial of June 5 I have received from Geneva the report of Yves M Biraud on "The Present Menace of Typhus Fever in Europe and the Means of Combating It." One fully realizes the great difficulty in summarizing this work in a short article or editorial. It however, would seem advisable to comment on one statement of Dr Biraud which you quote in your editorial to the effect that "As regards live vaccines the new method of Blanc (biliated flea virus) and that of Laigret-Durand (mouse brain) are the only ones that can be considered for the preparation of vaccine intended for Europeans."

Biraud gives much reported evidence of the value and earlier use of the Blanc vaccine, which consists of a dried murine virus in feces of infected fleas to which ox bile is added before inoculation. Among these he states, "mention should be made of the observations reported by Gonnet (1942), who in the Oujda region, where a vaccination campaign with the dried vaccine had been carried out in May 1941, saw cases (115) of benign typhus about mid-July in the tribes vaccinated. Some of these cases were of very short duration and suggested to him late vaccinal reactions. In 6 cases admitted to hospital, 5 of which were military cases he diagnosed vaccinal murine typhus." Biraud adds "it is hoped, therefore, that many and precise observations will be published to verify its innocuousness for Europeans." Owing to present circumstances he is not in possession of the most recent observations concerning the use of live vaccines in North Africa during the last epidemic year."

Some of these very recent reports reveal that many individuals inoculated with the Blanc live vaccine have developed typhus fever following the vaccination.

SULFADIAZINE CRYSTALLURIA AND THE INFLUENCE OF p_H ON THE THERAPEUTIC EFFICIENCY OF SULFONAMIDES

To the Editor—In the editorial comment "Prevention of Sulfadiazine Crystalluria" (THE JOURNAL, May 29) the question is raised whether alkalization modifies the therapeutic efficiency of sulfadiazine.

The relationship between p_H and sulfonamide activity has been described in a paper by Fox and Rose entitled "Ionization of Sulfonamides" (Proc Soc Exper Biol & Med 50 142 [May] 1943). Experimental data were presented showing that antibacterial activity resided in the sulfonamide anion rather than the unionized molecule and that raising the p_H increased the activity of the sulfonamides in proportion to the increased ionization that resulted. In addition, the greater potency of sulfadiazine and sulfathiazole as compared to sulfapyridine and sulfanilamide was shown to be a consequence of the fact that at physiologic p_H sulfadiazine and sulfathiazole are far more extensively ionized than sulfapyridine and sulfanilamide.

Similar results have been reported by Schmuelkes and his co workers (Proc Soc Exper Biol & Med 50 145 [May] 1942) and by Cowles (Yale J Biol & Med 14 599 [July] 1942). The importance of these studies to the mechanism of sulfonamide action has been commented on in an editorial

"Basicity and Drug Action" (Lancet 2 648 [Nov 28] 1942). Subsequently Bell and Roblin extended these observations to a variety of sulfonamide derivatives (J Am Chem Soc 64 2905 [Dec] 1942).

These studies have now been applied to the problem of the local use of soluble sulfonamides in war wounds and burns (work done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University). Bedside p_H measurements (with the glass electrode) of infected wounds have shown values ranging from p_H 5.5 to 6.5. In this acidic range from 10 to 100 times more sulfanilamide is needed for bacteriostasis but only 1 to 4 times more sulfathiazole or sulfadiazine is required. Since the solubility of these drugs is likewise reduced in acidic exudates, their sodium salts have been used locally with salutary results. The prompt control of infection with no tissue irritation (Fox, C L. Sodium Salts of the Sulfonamide Compounds Arch Surg 45 754 [Nov] 1942, THE JOURNAL, Dec 26, 1942, p 1401, Bull New York Acad Med to be published).

This principle of increasing ionization (soluble salt formation) with increasing p_H has been applied clinically to the prevention of renal precipitation and full details have previously been reported from this laboratory. Hydrogen Ion Concentration and the Solubility of Sulfonamides in Urine (with Dr Jensen, J Urol 49 334 [Feb] 1943), the Prevention of Renal Obstruction During Sulfadiazine Therapy (with Dr Jensen and Lieutenant Mudge, THE JOURNAL, April 3, 1943 p 1147).

WELFARE OF LABORATORY ANIMALS

To the Editor—As a result of recent correspondence with a number of workers engaged in experiments on animals I have become aware that there is a strong and widespread desire for experience to be pooled so as to enable the maximum of consideration to be shown for the feelings of laboratory animals. With the view of helping to give effect to this desire we have supplied to 130 laboratories on request, a copy of the recent book Veterinary Anaesthesia by Prof J G Wright, FRCVS.

At the suggestion of a number of research workers we are proposing further to compile information relating to (1) anaesthesia of rats, rabbits, guinea pigs and other animals not covered by Professor Wright's book, (2) methods of killing laboratory animals, (3) living conditions housing, diet and so on and to invite a small number of experienced men to act as a panel for approving or amending the resulting compilation. We should be most grateful to any readers of THE JOURNAL who would get into touch with us with a view to communicating to us any views or suggestions they may be able to offer.

The breeding of laboratory animals is regularly discussed among research workers and many of them think it would be desirable to put it as far as possible into the hands of trained personnel. We consider that this plan is likely to benefit the animals since it will offer an opportunity of bringing their living conditions under the supervision of responsible persons whose interest is not purely mercenary.

HYPERTENSIVE TOXEMIA OF PREGNANCY

To the Editor —Dr. Lewis Dexter and his associates in a paper published in *THE JOURNAL*, May 15, enumerate a considerable number of factors which "toxemia is not primarily due to," among them overactivity of the posterior pituitary gland. The past three years have witnessed great clarification in this problem.

Since 1918 I have advocated the tenet that, in the causation of the syndrome termed late toxemia of pregnancy, consideration of hyperdynamic posterior pituitary principles may bring us within measurable distance of the realities of the situation. In 1933 it was argued that a number of seemingly unrelated investigations have converged so that it may be reasonably concluded that toxemia represents disordered autonomic physiology as the result of undue posterior pituitary (pitressin) stimulation (*Am J Obst & Gynec* 26:311 [Sept] 1933). Efforts to identify in the blood an excess of the pressor-antidiuretic pituitary principle stirred much comment with denials of positive findings in late toxemia in preponderance. Reference to such negative findings and the failure in their investigations to reproduce in rabbits and rats hypertension and specific kidney lesions by posterior pituitary injection are the premises on which Dr. Dexter and his associates negate the etiologic importance of the postpituitary gland. Opposed to their position is an array of facts in favor of my view. The striking similarity between the cardinal features of blood chemistry in eclampsia and in experimental hyperpituitarism in dogs, the consistently present melanophore expanding principle in the blood in toxemia, as well as the corroborated clinical evidence of an increased susceptibility of toxemic individuals to pitressin, had first call. In extensive studies Knepper found changes in various organs as the result of repeated use of posterior pituitary injection yet was able faithfully to reproduce the well known lesions in vital organs in eclampsia by first parenterally administering proteins and subsequently posterior pituitary injection to laboratory animals. The biologic significance of the well known detachment into the maternal circulation of chorionic tissue, fetal proteins, thus apparently paving the way for the susceptibility of vital organs to the effect of pitressin was illustrated. Finally, atony and dilatation of the ureter, known to be constant concomitants of gestation and amenable to the influence of the posterior pituitary principle (*Bull Johns Hopkins Hosp* 42:118 [March] 1928, *J Urol* 20:413 [Oct] 1928), are unusual in preeclamptic toxemia, suggesting the effect of the pituitary factor. Chandra Mukherjee recently elaborated on these aspects of the problem and demonstrated in the blood the principles responsible for the vasopressor, antidiuretic and melanophoric effect in toxemia (*J Obst & Gynec Brit Emp* 48:586 [Oct] 1941), while Griffith produced in rats permanent hypertension by small repeated doses of pitressin injected intraperitoneally. The most recent experimental studies of Netzel shed further light on the transcendent importance of pitressin in the origin of liver and kidney lesions in eclampsia (*Vascular Spasm*, University of Illinois Press, 1943).

Current interest attaches to the recent discovery of the existence during normal gestation of a delicately balanced equilibrium between a set of factors effecting arteriolar hypertonicity and placental acetylcholine, and the dislocation of this equilibrium in toxemia resulting in the unopposed action on the vascular tree of naturally secreted vasopressin (*West J Surg* 49:615 [Nov] 1941). The investigations of C. Heymans revealing the automatic regulation of blood pressure by the action of pressoreceptors and their ready response to pressor changes and to acetylcholine serve to supply an additional key consistent with these views, which aim to convey a unifying and constructive concept of the pattern of the hypertensive toxemia of pregnancy.

J. I. HOFBAUER, M.D., Cincinnati

RED CELL TRANSFUSIONS

To the Editor —I read with interest the report of Dr. Howard L. Alt on "Red Cell Transfusions in the Treatment of Anemia" (*THE JOURNAL*, June 12, p. 417). I fully agree with the author regarding the usefulness of red cell transfusions but would like to point out the desirability of utilizing red cells in the form of concentrated suspensions rather than suspensions diluted with isotonic solution of sodium chloride. After a considerable trial we abandoned the addition of saline solution following aspiration of plasma both on account of technical disadvantages as well as because the addition of isotonic solution of sodium chloride to the red cells which have been stored in citrate-saline solution results in increased erythrocytic fragility and often detectable hemolysis. But we add, preferably at the time of collection of blood, 25 cc of a 50 per cent dextrose solution for a better preservation of red cells. The method in use at our hospital has been described elsewhere (Blum, Leon L. The Present Day Status of Combined Blood-Plasma Bank, with Reference to the Use of Concentrated Red Cell Suspensions, *J Indiana M A* 36:187 [April] 1943). We have used concentrated red cell suspensions (erythrocyte concentrates) in various anemic states after three weeks of preservation with dextrose with fully satisfactory clinical and hematologic results. There were no untoward reactions whatever. It is my impression that the percentage of reactions following red cell transfusions is even lower than that following whole blood, but a larger series of observations is needed to justify any definite conclusions.

Quantitative fragility tests performed on preserved red cell suspensions revealed a satisfactory state of preservation after three weeks.

In spite of the fact that these concentrated red cell suspensions are of rather heavy consistency, a satisfactory flow can be insured in most cases with an increase in height in the level of the bottle. We did not find it necessary to incorporate a Riddell's pump for administration of suspensions, as suggested by Watson (*Lancet* 1:107 [Jan 23] 1943).

I feel that erythrocyte concentrates represent the method of choice for red cell transfusions and that the use of red cell transfusions in anemic states should be greatly encouraged so that they will come into common use in civilian and military practice.

FAMILIAL TUBEROUS SCLEROSIS

To the Editor —Will you enter our opinion as to diagnosis on the father and son described under the heading of "Familial Tuberous Sclerosis (Epiloia) Without Adenoma Sebaceum" in *THE JOURNAL*, June 12?

From the data presented in this article it would seem to us that the entire clinical picture in case 1 could best be explained by the diagnosis of toxoplasmic encephalitis. This diagnosis is possibly applicable also in case 2, but in view of the absence of ocular abnormalities or widespread calcified lesions in the cerebrum there is insufficient evidence for this or any other diagnosis. There are several reasons why the diagnosis is at some moment in such cases, not the least of which is the fact that toxoplasmosis may lend itself to therapy rather better than tuberous sclerosis.

MEDICOLEGAL ABSTRACTS

Malpractice Chronic Osteomyelitis Following Extraction of Tooth—Marquess, a dentist practicing in Fresno, Calif, in the employ of Kennedy, another dentist, was consulted by the plaintiff, July 22, 1938, relative to a toothache. He discovered a deep carious condition in the second lower left molar, which he cleaned and into which he inserted a temporary filling instructing the patient to return in four days or sooner if suffering from pain. After returning home the patient became feverish and suffered such pain that she was confined to bed. Three days later she was taken to the dentist's office. The tooth was extracted after two injections of cocaine had been given—one "to effect a mandible block" and the other in the tissues adjoining the tooth. According to the patient, the dentist "did not apply iodine or any other solution to her gums before injecting the cocaine," nor did he take or recommend the taking of a roentgenogram of her teeth. According to the dentist, there was no infection of the tooth or in the socket from which it was extracted. After the extraction, the gums were sutured and the patient was instructed to wash her mouth with warm salt water and to apply ice packs. She was then taken home and put to bed. The next day she returned to the dentist's office. Her jaw then was swollen and she was suffering much pain. What the dentist did on this visit is not made clear in the reported opinion. She returned home to bed, but her condition became worse and her family physician was called and found her temperature above normal and her jaw infected. Under his treatment her condition was so improved that she was taken to see the defendant dentist again on July 30 when he advised her to consult a specialist which was done. Subsequently she was hospitalized for fourteen days during the first four of which she was in a semicomatose condition. Abscesses which had formed inside the lower jaw beneath the socket from which the tooth had been extracted and under the chin were lanced from the outside and drained. The gum was also lanced and drained. In January 1939 a diagnosis of chronic osteomyelitis of the left mandible was made at a hospital in San Francisco. On March 27 an incision was made under the jaw at the site of the previous lancing and bone and granular substances were removed. An incision was also made in the surrounding gum tissues and bone was removed and the sockets curetted. Following these procedures she was confined in the hospital until April 9. In December 1939 another abscess which was forming was drained. As late as July 1940 apparently the patient was receiving treatment for her condition. She instituted suit for malpractice against Marquess, the dentist who originally had treated her, and against Kennedy, his employer. The trial court granted a motion for a nonsuit and entered a judgment in favor of the defendants and the patient appealed to the district court of appeal fourth district, California.

At the trial a dentist practicing in Fresno was called as a witness by the plaintiff and testified that according to the standards of the practice of dentistry prevailing in Fresno, the town in which the dental services in question were performed the defendant Marquess should have had a roentgenogram taken before extracting the tooth and should have applied iodine or some other disinfectant to the gums before inserting a hypodermic needle in them and extracting the tooth. Since said the appellate court where a motion for a nonsuit is granted, we must accept as true any substantial evidence tending to

support a judgment for the plaintiff, we must take the following facts as established in this case. That the standards of practice of dentistry in Fresno required that defendant Marquess have an x-ray film taken or at least recommend that an x-ray be taken of the aching tooth and jaw, and also that he sterilize the gums before inserting the hypodermic needle and pulling the tooth, that he did neither of these things and therefore did not employ the training, care and skill required of dentists of good standing practicing in the community. If this failure on the part of Marquess was the proximate cause of the infection from which the patient suffered, the nonsuit was erroneously granted. We may also accept, continued the court, as established facts that immediately after the extraction there was no infection on the roots of the tooth or in the sockets and that a serious infection set in which caused the plaintiff much suffering and expense over a period of two years.

As corroborative of the correctness of its view, the court discussed at some length *Barham v Widing*, 210 Cal 206, 291 P 173. In that case a dentist was accused of malpractice because he failed to sterilize the hypodermic needle used in injecting an anesthetic, and to sterilize the gums before extracting a tooth.

In that case the Supreme Court of California said

Under the circumstances of this case there is a remote possibility that the infection developed from some cause other than the defendant's failure to sterilize the needle or the gum into which it was inserted, but the evidence is sufficient upon which to warrant the jury in finding that it was caused by his negligence in failing to follow these reasonable precautions in spite of his testimony to the contrary. The jurors were entitled to accept the solution to which these circumstances led them in preference, even, to the positive statements of the defendant and his nurse to the contrary. After the verdict of a jury has been fairly rendered all the circumstances of the case, together with every reasonable inference which may be drawn therefrom, will be marshaled in support of the judgment. Because of the very subtleness of the origin and development of disease, less certainty is required in proof thereof. As the court says in the case of *Dimock v Miller*, 202 Cal 668, 671, 262 P 311, 312

"If it is necessary to demonstrate conclusively and beyond the possibility of a doubt that the negligence resulted in the injury, it would never be possible to recover in a case of negligence in the practice of a profession which is not an exact science."

It is not necessary in the trial of civil cases that the circumstances shall establish the negligence of the defendant as the proximate cause of injury with such absolute certainty as to exclude every other conclusion. It is sufficient if there is substantial evidence upon which to reasonably support the judgment. *Ley v Bishop*, 88 Cal App 313, 316, 263 P 369.

It was not necessary for any dentist or physician to state that the conduct of the defendant was negligent or in conflict with the usual established practice of the profession in that vicinity to administer a local anesthetic for the purpose of extracting a tooth without sterilizing the needle or the flesh into which it is inserted. The court will take judicial knowledge of the necessity to use ordinary care to procure sterilization under such circumstances.

The defendant dentist sought to distinguish the facts in the present case from the Barham case, because there the infection started from the exact spot of the injection, while here it was in the general locality but not necessarily in the exact spot of the injections. This distinction, said the court, is too tenuous to be sound. Here the infection was in the region where the needle pierced the unsterilized gums, and the reasonable inference might follow, if drawn by the jury, that a germ on the unsterile gums was carried into the tissue on the needle and caused the infection. The result of an unsterile condition is a matter of common knowledge under the cases already cited.

The defendant dentist next argued that, assuming there was a failure to conform to the standards of good practice of dentistry in Fresno, still there is nothing in the record to establish that this lack of care was the proximate cause of the infection. The same argument, said the court, was made and rejected in the

Barham case just cited. A like argument was advanced by the defendant dentist in *Dimock v Miller*, 202 Cal 668, 262 P 311, in which a dentist was accused of malpractice in failing to sterilize his needle before giving a hypodermic injection and in using impure water in the solution injected. It was held in that case that a plaintiff was not required to exclude all factors, other than those mentioned, as causes of the infection. Where the results of negligence on the part of a physician or dentist, continued the court, are peculiarly within the knowledge of expert witnesses, the testimony of those expert witnesses is a necessary element of a plaintiff's case. The danger of infection from an unsterile instrument, or a dirty field of operation, is a matter of such common knowledge that a jury is authorized to draw the reasonable inference that an infection was caused by negligence when an unsterile instrument is used, or the operative field is not properly sterilized.

As further corroborative of the correctness of its holding, the district court discussed *Roberts v Parker*, 121 Cal App 264, 8 P (2d) 908, in which a dentist was sued for malpractice when osteomyelitis of the jaw bone set in after an extraction had been performed and in which no roentgenogram had been taken prior to the extraction to determine the condition of the field of operation. In that case expert witnesses testified that under the standards of good practice prevailing in the community a roentgenogram should have been taken before the tooth was extracted. There was evidence introduced on behalf of the dentist tending to prove that the disease had its source other than in the extraction of a tooth. It was argued that here was nothing to show that the failure to use due care on the part of the dentist was the proximate cause of the osteomyelitis.

In disposing of this argument the court in the Roberts case said

Therefore, if in spite of the testimony tending to show a different origin of the disease there be testimony to sustain the opposite conclusion which has been reached by the jury, its verdict must be sustained. In other words after the verdict of the jury has been fairly rendered, all the circumstances of the case, together with any reasonable inference which may be drawn therefrom will be marshaled in support of the judgment. Measured by the foregoing rules, the circumstances of the present case are legally sufficient to sustain the jury's verdict.

A like rule, continued the court, must be invoked when the trial court grants a motion for a nonsuit.

The district court of appeal concluded that there was some substantial evidence in the record and that reasonable inferences could be drawn from that evidence, pointing to the lack of due care on the part of the defendant Marquess as being the proximate cause of the disease suffered by the plaintiff. It follows, in the opinion of the court, that questions of fact were presented for the decision by the jury and that the motion for a nonsuit was improperly granted by the trial court. Accordingly, the judgment, in effect, dismissing the suit was reversed. *Mastro v Kennedy*, 134 P (2d) 865 (Calif, 1943).

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Hereditary Cataracta Cerulea: Six Related Cases O Wolfe and R M Wolfe—p 404

Virus Isolated from Pemphigus-like Keratoconjunctivitis—Gallardo and Hardy report a case of severe chronic cicatrizing keratoconjunctivitis with pannus, similar in appearance and course to ocular pemphigus. A presumptive diagnosis of ocular pemphigus was made. A virus designated as S virus, close to if not identical with vaccinia virus, was isolated from conjunctival scrapings during three different periods of exacerbation of the disease. Typical elementary bodies and cytoplasmic inclusions like those of vaccinia were found. The virus was isolated by rabbit cornea and by mouse brain inoculations as well as by inoculation of the chorioallantois of the developing chick embryo. The close relationship to vaccinia virus was demonstrated by neutralization tests in which vaccinia immune serum neutralized the S virus, and anti-S serum neutralized vaccinia virus. The relationship of the virus to the keratoconjunctivitis must remain an open question until observations in other similar cases become available.

Bronchiectasis and Dextrocardia: Observations on Etiology of Bronchiectasis A M Olsen—p 435

Gastric Lavage and Sputum Cultures—Robinson and Dunn state that a thousand consecutive bacteriologic examinations of gastric lavage specimens confirm the reported efficiency of this procedure. They recommend the use of a small caliber, soft rubber tube to collect the material and of small amounts of water for lavage. Inoculation of culture mediums and/or guinea pigs with as much as possible of the material obtained is necessary for best results. Microscopic examination of the stained sediment is not adequate. Examination by culture and/or animals of simultaneously obtained sputum and gastric lavage material from persons whose concentrated sputum has been previously found microscopically negative will yield more positive results than will examination of either material alone. A gastric lavage examination should be made of all persons who have a negative sputum or no expectoration and are suspected of having pulmonary tuberculosis. It is also indicated for patients under treatment for pulmonary tuberculosis when the sputum becomes scanty or inconstant in amount or when they cease to expectorate.

Chorioallantoic Membrane of Chick Embryo for Testing Tubercle Bacilli—In order to check the relative virulence of the two substrains H37-Rv and H37-Ra suspensions were implanted by Emmart and Smith on the chorioallantoic membrane of the nine day chick embryo and also inoculated into guinea pigs. Within six days after implantation 96 per cent tubercle formation was present in the membranes implanted with the strain H37-Rv while only 18 per cent tubercle formation was present in those implanted with the avirulent strain H37-Ra. Corresponding differences in invasiveness of the two substrains were found in guinea pigs. Only 1 guinea pig inoculated with H37-Ra died within one hundred and ninety days.

while 100 per cent of those inoculated with H37-Rv died within the same period. Thus the chorioallantoic membrane of the chick embryo can be successfully used to determine differences in virulence between closely related substrains of tubercle bacilli.

Epidemic of Erythema Infectiosum—Chargin and his associates report an outbreak of erythema infectiosum in a New York orphanage which housed 137 children, 80 of which were attacked. There were observed eighty primary attacks and ninety relapses, a total of one hundred and seventy attacks. The relapses numbered from one to six. The most severe attacks and the greatest number of relapses were among the girls. Next in order of frequency and severity were the group of older boys. The mildest attacks occurred among the younger boys, no relapses were observed in this group. In 64.7 per cent the eruption was limited to the face, in 23 per cent to the body and in 33 per cent to the face and the body. Infants and children between the ages of 1 and 4 years were relatively immune. Seventy of the eighty primary attacks occurred within the first thirteen days following the outbreak. The relapses appeared in cycles. Laboratory and epidemiologic studies failed to throw light on the causation. The disease is apparently not transmitted by carriers. The disease is not reportable but should be so made as to make possible etiologic and epidemiologic studies. The incubation period appears to have been from one to twelve days.

Rapid Treatment of Early Syphilis—Thomas and Wexler report the results of treating 782 patients by the rapid method. Mapharsen 0.06 Gm was given morning and evening for ten days. Later the treatment period was shortened to six days in order to avoid an occasional "ninth day erythema." The patients were now given 0.1 Gm morning and evening for six days. Thus the dose per day was increased from 0.12 Gm

to 0.2 Gm, but the total amount for the course remained unchanged at 1.2 Gm. Under this plan no serious toxic reactions were noted until the one hundred and eleventh patient, a woman, died of hemorrhagic encephalitis. Efforts were made to find the dose that would be neither great enough to endanger the abnormally sensitive nor small enough to penalize the average patient by unduly protracting his disease. Relapses were more frequent among patients who received less than 0.9 Gm of mapharsen. Attempt was made to enhance the therapy by combining fever treatment with it. This apparently did nothing to prevent rare cerebral reactions but permitted the authors to obtain better therapeutic results from smaller doses. The results of treating early syphilis either with a total dosage of 1.0 Gm or more of mapharsen or with a combination of fever and less than 0.9 Gm of mapharsen compare favorably with the results of prolonged continuous routine treatment.

Pneumonia Complicating Mild Respiratory Infections—Becker emphasizes that lobular atelectasis occurring in the course of acute respiratory infection is much more common than is generally supposed. Radiographically it simulates bronchopneumonia. Some degree of infection is frequently present distal to bronchial obstruction. The clinical course, usually benign and brief, is apparently determined by such factors as size, location and number of bronchi involved and the degree of blockage together with the dosage and virulence of infection distal to the bronchial occlusion. Localized crepitations, tubular breathing and dullness are often absent. Even slight differences in breath sounds and resonance in a patient suffering from a respiratory infection warrant a suspicion of a pulmonary complication. In most instances x-ray study alone will afford adequate information. Considerable variation exists in the onset and clinical course of such respiratory episodes, ranging in extent from a picture simulating severe "flu" or grip or a heavy chest "cold" to an ambulant status presenting only extremely mild symptoms. No studies have established a clear cut virus causation for this class of bronchopneumonia. Until satisfactory laboratory studies to the contrary are completed, such pulmonary infections are best explained on a basis of partial bronchial obstruction with distal infection.

Primary Atypical Pneumonia of Unknown Cause—Meakins says that between June and November 1942 approximately 150 cases with the eventual diagnosis of lobar pneumonia, bronchopneumonia and pneumonitis were admitted to his hospital. He thinks that the great majority of these "pneumonias" were what could be termed "primary atypical pneumonia, etiology unknown." He presents an analysis of the data on 100 cases which suggest that this disease entity might easily be

mistaken for severe coryza, grip" or bronchitis. X-ray examination of the lungs always showed infiltrative changes and 90 per cent of the cases gave physical signs. Cough was the main complaint. Usually a normal leukocyte count was found. The course of the disease was mild. No dangerously ill patients have been seen and there have been no deaths.

Furunculosis—Etiology and Treatment B Barnes—p 243

Furunculosis—Barnes reports observation on furunculosis in 16 college students between the ages of 17 and 25. No correlation was apparent between the hemoglobin values and the development of boils; there was no evidence of malnutrition and no local skin conditions contributing to the development of furunculosis. The basal metabolic rate or basal temperature was below normal in each case. Thyroid 1 grain (0.06 Gm) a day was given and further boils did not develop during the period of this therapy. In myxedema the blood flow per minute and the skin temperature are reduced but with thyroid medication are restored to normal. Since the healing process is accompanied by an increase in circulation it is not surprising that thyroid therapy would aid in skin infections of persons with poor peripheral circulation.

Vitamin D Therapy in Prevention of Rickets—Wolt gave 600,000 U S P units of an electrically activated preparation of ergosterol divided in two oral doses in precooked cereal and milk to 75 infants between the third to fifth month of life. Massive doses of vitamin D were well tolerated. No toxic manifestations were observed. No diminution in the incidence of respiratory infections was noted. There is no danger in administering a single massive dose of vitamin D to young or premature infants. The danger lies in repeating these large doses over a period of time so that several million units of vitamin D are given. Large doses may be toxic if repeated daily. Two plans are outlined. One is to protect the infant until 2 or 3 months of age by means of daily prophylactic doses of 1,000 units of vitamin D and then to administer a single dose of 600,000 units. The latter dose may be repeated from four to six months later. The other plan is to give an infant at 1 and 2 months of age respectively 50,000 units of vitamin D in formula and then at about 3 months of age to administer a single dose of 600,000 units in precooked cereal. This single dose may be repeated from four to six months later. There is experimental evidence that vitamin D when given in single massive doses is stored in the blood plasma and the tissues for weeks or months. This evidence is borne out by clinical observations. The oral single massive dose prophylaxis of rickets is to be preferred to the parenteral method. Only in severe

intestinal disturbances or for young premature infants whose absorption may be poor is it necessary to use the parenteral method. The single massive dose of vitamin D is effective, safe and time saving.

Fatal Agranulocytosis Following Sulfathiazole Therapy—Kato and his associates report a case of acute and fatal agranulocytosis with toxic dermal lesions produced by therapeutic doses of sulfathiazole in an infant 8 weeks old. Despite the fact that absolute proof of the sulfonamide being the sole cause of agranulocytosis is lacking, the circumstantial evidence in the case strongly suggests that both intoxication by and sensitization to this drug played significant roles in the production of the toxicodermatosis as well as of the agranulocytosis which resulted in the death of the patient.

Orthostatic Albuminuria—Young and his associates show that in each of 4 patients rejected by the medical examining boards because of albumin in the urine the albuminuria was orthostatic in character. The examining boards now accepted these men. The diagnostic value of placing the patient in an exaggerated lordotic position is emphasized. Sixty-seven cases diagnosed as orthostatic albuminuria were studied from the records of the Johns Hopkins Hospital. Three of these were shown to be cases of nephritis. In the remaining 64 no evidence of nephritis developed, and repeated examinations in some showed the urine to be free from albumin at various periods after admission. Orthostatic albuminuria is a harmless condition which generally disappears early in adult life. The following criteria should be met: (1) no past history of renal disease, (2) normal blood chemistry, nonprotein nitrogen, blood urea, total protein and albumin-globulin ratio, (3) normal kidney function (phenolsulfonphthalein, urea clearance, and dilution and concentration tests), (4) no leukocytes, erythrocytes or casts in the urine, except intermittently and in small numbers, (5) no elevation of the blood pressure, (6) negative plain x-ray films and intravenous urograms, (7) absence of albumin in the urine secreted and voided when in the recumbent position. Young men rejected by medical examining boards because of albuminuria could probably be shown fit for service with the use of more comprehensive tests.

Infectious Gas Gangrene—Jablons and Krebs stress that infectious gas gangrene, particularly in war wounds, is a multiple infection. The micro-organisms concerned are members of the anaerobic group, either in pure culture or in association with aerobes. The authors list 21 pathogenic anaerobic organisms which have been isolated from infected wounds, 11 aerobes which have been found in association with anaerobes in clinical cases of infectious gangrene and 9 toxigenic anaerobic organisms which can give rise to a progressive toxic necrosis of tissue with or without general fatal intoxication. The best treatment, in addition to surgery, is a combination of antitoxin and chemotherapy with the sulfonamide group of drugs. Prophylactic serum for infectious (gas) gangrene to be of value must contain antibodies against the three most commonly occurring organisms. The curative treatment of infectious (gas) gangrene depends on the identification of the organisms present, since the serum must contain antibodies against these causative agents. The results of treatment with monovalent and polyvalent serum in the first world war and in civil practice since has shown that the mortality rate of 44.60 per cent in cases of infectious (gas) gangrene can be reduced to 9.12 per cent by the use of anti-Welch-septicum-oedematis serum. Surgical excision is of value as a prophylactic measure. It is not curative in advanced cases. Infiltration of the tissues by the anaerobes in advanced cases makes multiple incisions of little value. Chemotherapy with the sulfonamide drugs or zinc peroxide has some value as a prophylactic measure in delaying development of the infection. Its efficacy in combating advanced anaerobic infections has not been proved.

Acute Craniocerebral Trauma.—The material presented by Gurdjian and his associates comprises the results of observations made on postmortem examinations of 151 patients who died following cranial trauma. They show that in practically every instance or fatal head injury there is a combination of pathologic processes. For example, although the chief lesion may be an epidural hemorrhage, petechial hemorrhages and cerebral bruises frequently coexist. There is great variation in the extent and severity of brain lesions in the fatal cases. Among some few pathologic lesions were noted to explain the cause of death. However, gross lesions were found in every case. A massive intracranial hemorrhage due to trauma is usually on the surface of the brain and may be amenable to surgical treatment. Large intracerebral clots are rare. In epidural hemorrhage, exploration about a fracture line seems justifiable. In subdural hemorrhage, a fracture line is of little value in localization, often being opposite to the side of the subdural hemorrhage.

Paraphysal Cysts of Third Ventricle.—Weinberger and Boshes point out that the small benign encapsulated cystic tumors occupying the third ventricle of the brain formerly eluded the neurologist. Cerebral pneumography and modern refinements of neurosurgical technique have made possible the diagnosis and the removal of these tumors. The authors report a successful removal of a paraphysal cyst which brings the total number of reported surgical recoveries to 17. Paraphysal cysts are now recognized as arising from the paraphysal body, an ancient gland situated in the midline of the rostral portion of the roof of the third ventricle. A syndrome diagnostic of these tumors is lacking, but the occurrence of violent headache influenced by posture is regarded by some as significant. Operation for a paraphysal cyst should be performed in one stage. Ample working room is obtained within the dilated lateral ventricle. The structures are seen clearly with the aid of illuminated retractors which may be easily introduced within the ventricle. The foramen of Monro may be found by following the choroid plexus forward until it is seen to disappear. The cyst, if large, presents itself as a greenish or bluish mass in a dilated toramen. If small, it may not be visible and the foramen may appear as a small slit. By tugging gently on the choroid plexus, one can bring the cyst wall into view in the aperture of the toramen. In the reported case it was possible thus to tease the cyst through the toramen. Some operators first evacuate the thick colloidal contents of the cyst by aspiration and then deliver the capsule through the toramen. Others enlarge the toramen by slitting its margin. The slit can be made safely only in the anterior rim of the toramen. The occurrence of cerebral swelling as a consequence of operative

manipulations, may require drainage of the ventricle for a few days with a Penrose drain or an indwelling cannula. If a patient survives the operative procedure and the immediate postoperative course, a complete recovery is to be expected. From this point of view, paraphysal cysts are extremely favorable tumors.

Detergents in Cleansing of Burns.—According to Rosenberg, most workers are of the opinion that vigorous cleansing methods have no place in the preliminary treatment of burns because (a) anesthesia is required, (b) shock is thereby increased and (c) injury to remaining healthy tissue results. In many burns the tanning or coagulation method or local treatment seems to possess advantages, but infection arising from beneath the eschar speaks for the inadequacy of preliminary cleansing procedures. Certain of the synthetic detergents employed in one of several combinations act as cleansing agents in the local treatment of burns. Their unique properties which make them superior to other cleansing agents are (a) their ability to penetrate and 'solubilize' substances such as greases, oils and fats as well as particulate matter, (b) their lack of irritating or tissue-damaging properties, (c) their antiseptic nature and (d) the fact that after all grease, including the normal skin oils, is removed, the subsequent take of dye or tanning agent is rendered easier and a proper eschar more readily formed. In clinical tests with a number of detergent mixtures performed both on controls with normal intact skin and on 25 patients with relatively mild second degree burns, the properties listed were substantiated. More than three-fourths of the burns when first observed in the emergency service of a metropolitan hospital were covered with grease, oil, rats or ointments. Burns covered with grease and oil, the result of military engagements, represent a problem in which the application of these new cleansing agents may be of specific benefit.

Injection of Varicose Veins.—The method described by Bellis and Churney has been employed successfully in a large series of cases in the surgical service of the O'Reilly General Hospital, U. S. Army, Springfield, Mo., and in the surgical outpatient clinic of the University of Minnesota Hospital, Minneapolis. With the patient sitting on the table and the lower extremities on a nearby stool or simply flexed over the side, one of the most distal varicose veins, one usually around the ankle, is selected. A No. 25 gage needle to which is attached a syringe containing 3 to 5 cc. of a sclerosing solution is inserted into the vein at the most convenient distal point. With the syringe held firmly in place but without injecting any of the sclerosant, one brings the patient's lower extremities carefully onto the table. The patient lies horizontally and the affected extremity is elevated by an assistant to at least 45 degrees. As much as possible of the blood contained in the veins is permitted to drain into the deep system and when the extremity appears pale, the sclerosant is injected into the ankle vein and the needle removed. No bleeding occurs from the needle puncture, since the point of injection is elevated above the level of venous pressure. A small dry dressing is placed over the puncture site and an elastic bandage wrapped from the ankle to the middle of the thigh. The extremity is then placed on several pillows and the patient allowed to remain in that position for twenty minutes following which he is allowed to be ambulatory. Any of the popular sclerosants may be employed. The authors used 5 per cent sodium psyllate. With this simple technique a single injection was usually sufficient while a few have been given two injections.

Anomalous Forms of Amaurotic Idiocy—Wyburn-Mason presents a number of typical and atypical cases of amaurotic idiocy and furnishes evidence that two types of the disease exist. 1. An infantile type, mainly confined to Jews, which is usually, but not always, rapidly fatal and almost always begins before the third year. Occasionally only optic atrophy occurs instead of the usual macular cherry-red spot. It is probably related to Niemann-Pick's disease. 2. A juvenile type, with onset chiefly at about 6 to 8 years of age, but sometimes as early as the second year or as late as the twenties. It occurs chiefly in non-Jews, has a slower course and also occasionally shows optic atrophy instead of the pigmentary macular changes, the final retinal picture resembling retinitis pigmentosa. It is unrelated to the infantile type genetically or histochemically and its relationship to macular heredodegeneration is doubtful. Often only cerebral or retinal changes are present in older cases.

Sulfonamide Therapy in Cerebrospinal Fever—Beeson and Westerman base this study on 3,575 cases of cerebrospinal fever which were submitted to the Ministry of Health by more than a hundred widely scattered hospitals of England and Wales during the two year period June 1939 to June 1941. All but 19 patients were treated with sulfonamides, and 965 of them

received some form of specific serum therapy. The disease occurred most often in infants and young children, 45.5 per cent of the patients being under 15 years of age. The ratio of males to females was 6 to 4. The fatality rate for all patients was 15.94 per cent, it was greatest at the extremes of life and least in the 15-19 years age group. Thirty-eight per cent of the deaths occurred within twenty-four hours of the time of admission to the hospital. The most frequent complications were cranial nerve paralysis, arthritis and deafness. The case fatality rate in 2,591 cases in which sulfonamides alone were used was 14.3 per cent. In an additional 965 cases, in which serum treatment was combined with chemotherapy, the fatality rate was 18.8 per cent. The poorer result was probably due in part to the fact that serum was administered to more severely ill patients. There is no indication that the administration of serum as an adjuvant to sulfonamide therapy is beneficial. In the treatment with sulfonamides a considerable variation appears to be possible in dosage and duration of therapy without noticeable effect on the fatality rate. Statistically the results were about the same whether chemotherapy was begun early or comparatively late in the course of the disease. This can be attributed to the fact that the more severely ill tend to be sent to the hospital sooner than those who are mildly ill. The age of the patient is of distinct importance in determining the outcome of meningococcal infection even with the aid of sulfonamide therapy.

Chemotherapy and Serotherapy in Meningitis—Jubb reviews 3,206 cases of meningitis treated in hospitals either by chemotherapy plus serum or by chemotherapy alone and surviving more than twenty-four hours after admission. The fatality rate in the total number was 10.5 per cent, in the 849 cases treated with chemotherapy plus serum it was 13.8 per cent, in the 2,357 cases treated with chemotherapy alone it was 9.2 per cent. In the five years 1936-1940 there was a steady decline in the fatality of cerebrospinal fever, the annual rates being successfully 63.8, 61.2, 50.6, 34.2 and 20.2 per cent. In a series of cases treated in the period 1931-1934 with serum of improved quality and administered suitably the rate was 27.9, but a decrease of the rate for the whole country did not occur until the introduction of chemotherapy, with the wider employment since 1938 of the sulfonamide derivatives the decline has been dramatic. In 1941 the rate was 19.5 per cent and in the first half of 1942 it was 19.5, as against 19.9 in the corresponding periods in 1940 and 1941. It is possible, therefore, that 1942 will show only a slight further decrease.

Oxygen Therapy in Shock—Melton gave high concentrations of oxygen to patients with peripheral circulatory failure. In order to assess the effect of oxygen independently of other therapeutic measures such as transfusions and drugs, oxygen was frequently begun as soon as possible after the patient was admitted. Patients with shock treated fell into the following groups: (1) 8 patients with trauma due to accidents or operations, (2) 12 patients with nontraumatic hemorrhage, (3) 5 patients with peritonitis due to perforated viscus or strangulation and (4) 3 patients with postoperative lung complications. A small miscellaneous group of patients with peripheral circulatory failure and severe collapse were also studied and included 1 with asthma, 1 with pneumonia and 1 in diabetic coma. The observations show that oxygen is of benefit in shock. It raises the blood pressure and improves the pulse, color, mental alertness and well-being. The results can be readily understood in the cases in which there was considerable lung involvement as the cause of anoxia, but striking improvement was also obtained when the heart and lungs were not affected. The beneficial action of oxygen was seen in shocked patients during and immediately after an operation. It was also observed in patients who had not received an anesthetic immediately preceding the

shock. In some cases of profound shock, particularly in elderly but also in young persons improvement was not observed. This failure was sometimes found associated with continued hemorrhage, severe infection or uremia. In some of these cases oxygen may have helped to tide the patient over a critical period, even though immediate improvement was not obvious. There were 14 deaths despite the initial improvement in 12 of these fatal cases, but most presented a hopeless prognosis from the start of the treatment. Oxygen appears to be most useful in hemorrhage which has been arrested. Hemorrhage was a definite factor in producing shock in 17 of the patients and 13 of them improved with oxygen. With 13 patients hemorrhage was not a factor and 10 of these improved with oxygen therapy. With the exception of 2, the patients in this group were either suffering from pulmonary complications or were recovering from a general anesthetic. Oxygen cannot replace transfusions but must be regarded as an adjunct to such measures.

Sulfaguanidine in Paratyphoid B—McNair Scott and his collaborators tested sulfaguanidine in an outbreak of paratyphoid B in Liverpool during July and August 1941. The number treated with sulfaguanidine was 40 and there were 48 controls. The two groups appeared to be similar in all respects. The average age of the treated patients was 16.6 years or the untreated 15.5 years. Children under 5 years of age were excluded from the study. Sulfaguanidine was given for ten days. During the first five days the daily doses varied between 8 and 16 Gm. depending on the age of the patients and during the last five days between 4 and 8 Gm. Sulfaguanidine was used in the treatment of paratyphoid B fever in patients who were (a) acutely ill (b) convalescent (c) persistent excretors. During the acute stage no difference was seen in the course of the disease among the treated as compared with the untreated. In the convalescent stage there was no evidence that the patients treated with the drug excreted paratyphoid B organisms for any shorter period than the control group treated with kaolin. The drug failed to clear 4 persistent excretors of the organisms.

Anesthetic Explosion Due to Static Electricity Elva M. Chivers —p 527

Case of Matricide—A man aged 20 accused of the murder of his mother, was found guilty but insane. Hill and Sargent report that he had always been nervous and apprehensive, not particularly aggressive and had failed to adapt himself to ordinary life having become dependent on his mother. His meals had been irregular. Recently there had been some quarreling between the accused and his mother. On the morning of December 30 he had lost his temper and struck her, for which he had subsequently apologized. On that day he had eaten poorly, his last carbohydrate meal being at noon. In the evening he ate two small chops. Between 9 and 10.30 p.m. he had drunk 4 pints of mild ale and had then returned home. On his mother's return at 11 o'clock a quarrel developed during which he was pushed along a passage into his own room. Despite the 4 pints of beer he suddenly felt thirst and went to the kitchen to fetch an opener for a lemonade bottle. There he saw a kitchen knife and at this point he said something came over him—he 'was like a homicidal maniac'. He attacked his mother with a knife and killed her. A doctor who had examined the accused in 1941 suggested that an investigation be made of the carbohydrate metabolism and of the electroencephalogram. From the history and the examination it was concluded that the accused had an abnormal personality, a poor physique, severe inner ear deafness, a possible birth injury to the right hemisphere and psychopathic inheritance.

He was not suffering from epilepsy or mental disease, but whenever his blood sugar was below 100 mg per hundred cubic centimeters the electroencephalogram was abnormal and hyperventilation would induce an abnormal electrical discharge in the cortex associated with a degree of impairment of judgment and some clouding of consciousness. From the history of his diet before the murder and the sugar tolerance tests it was practically certain that his blood sugar was below 100 mg at the time when he murdered his mother and that hyperventilation occurred as the result of the emotion aroused by the quarrel and particularly by his being pushed struggling along a corridor. Since the murder took place over an hour after he had finished the beer the malt sugar would not have inhibited the phenomenon. The authors concluded that the accused knew what he was doing at the time he killed his mother and knew that it was wrong but that his brain was functioning abnormally at the time, the abnormality being such as to impair his judgment and render him unable fully to appreciate the nature of the act.

Heparin in Mesenteric Venous Thrombosis—According to Luke mesenteric thrombosis is the most lethal of the causes of bowel obstruction. The reported series show that the chance of survival is almost nil without operation. The operative mortality of resection averages about 50 per cent. The main factor of this high rate is a continuation of the thrombotic process beyond the limits of the resected bowel. It is here that the experience with heparin is encouraging. It occurred to Luke that in the early cases of mesenteric venous thrombosis in which it could be shown that the involved bowel was still viable, heparin alone would be a logical method of treatment. This plan was adopted for a man aged 42 whose history and physical signs suggested an early obstruction of the small intestine. When the abdomen was opened, early mesenteric venous thrombosis was diagnosed and it was decided to treat the patient with heparin alone. The drug was administered by intravenous drip (10 cc of heparin in 1000 cc of isotonic solution of sodium chloride). The total amount given in the course of ten and one-half days was 210 cc. The patient was out of bed on the fourteenth day and was discharged on the seventeenth. The author suggests that early cases of mesenteric venous thrombosis seen before serious intestinal infarction has taken place and when the bowel is definitely viable should be treated with heparin alone.

Sulfapyridine in Pfeiffer's Bacillus Meningitis—Moir reviews 4 cases of influenza meningitis in which sulfapyridine was used. Two of the patients, one a child of 10 months recovered. The number of cases described is too small for precise conclusions but from this experience the best form of treatment seems to be diagnostic lumbar puncture to be repeated only if restlessness and irritability become uncontrollable by other means or when the fluid might be expected to be sterile (i.e. when the clinical condition has much improved). The concentration of the sulfapyridine in the cerebrospinal fluid should be as high as possible and repeated lumbar puncture can serve only to reduce the concentration. Large doses of sulfapyridine should be given (never less than 3 Gm. in twenty-four hours) and reduced doses should be given for at least a fortnight after meningitic symptoms have disappeared. Fluids should be pressed in order to prevent renal complication. Dehydration and vomiting are best combated by intravenous drip saline, and this provides a convenient method for the administration of sulfapyridine which seems worth a trial in all cases of Pfeiffer's bacillus meningitis.

Bull. Health Organ, League of Nations, Geneva**10 1-76, 1943 Partial Index****Present Menace of Typhus Fever in Europe and Means of Combating It** Y. Biraud—p. 1***Contribution to Study of Metabolism of Vitamin C and Elimination in Urine** F. M. Messerli—p. 65

Metabolism of Vitamin C and Its Elimination in Urine—Messerli reports investigations on the elimination of vitamin C in the urine of Lausanne school children. A modification of the method of Grunder and Niederberger was used. The rate of excretion was on an average 1.4 to 1.5 mg. per hundred cubic centimeters in 1940-1941. This amount varied according to feeding and to the social conditions of the children. Body posture, rest, exercise and exposure to sun seemed to have no influence on the excretion. In saturation tests in cases of vitamin balance ingestion of ascorbic acid is followed quickly by an increase of excretion, this increase is not observed immediately in cases of vitamin insufficiency. This test might be used for control of vitamin C sufficiency. For this purpose the urine should be titrated three or four times every half hour after the ingestion of 0.05 Gm. of ascorbic acid. A rise in vitamin excretion would signify vitamin sufficiency, the absence of rise, vitamin insufficiency. Children who for a month received a daily preventive dose of 0.05 Gm. of ascorbic acid and whose vitamin excretion in the urine had greatly increased in consequence were absent from school on account of illness only half as frequently as their schoolfellows who did not receive vitamin C. Vitamin C saturation tests did not reveal any increase in albuminuria.

Schweizerische medizinische Wochenschrift, Basel**72 1141-1168 (Oct 17) 1942 Partial Index****Eczema and Eczema like Dermatitis** W. Lutz—p. 1141***Efficacy of Extrapleural Pneumothorax** M. Arnold—p. 1144***Cirrhosis Caused by Schistosomiasis and Cirrhosis in General** R. Jaffe—p. 1149**Riboflavin Metabolism in Two Patients with Generalized Eczema, Who Had Lived Chiefly on a Raw Diet** A. F. Kunz—p. 1154**Treatment of Diphtheria and Scarlet Fever in Institutions** W. Hoffmann—p. 1160

Extrapleural Pneumothorax—Arnold regards as indication for the extrapleural pneumothorax active, progressive, chiefly exudative and cavernous, usually febrile, pulmonary tuberculosis. The procedure is also indicated in relatively inactive, partly productive and partly exudative cavernous and perhaps subfebrile types. Total obliteration of the intrapleural space by a previous pleurisy or failure to produce an intrapleural pneumothorax or to improve it by thoracocautery are the prerequisites. A marginal group is represented by the inactive, nonprogressive, cirrhotic, cavernous and febrile pulmonary tuberculosis. Maurer's thoracoplasty, with the removal of five ribs in two stages, is much less dangerous for the heart. The author stresses care in the management of the costal gap, caution in the handling of the intercostal vessels, treatment of cough, avoidance of increase in pressure by refilling with air, avoidance of premature puncture of serous effusion, evacuation of infected collections of serum with local application of sulfathiazole, daily puncture of hematomas and refilling of dry pneumothorax. If these points are adhered to, pneumothorax will effect a cure and will avoid the disadvantages of plastic operations such as residual cavities, permanent collapse and disfigurement. On the basis of observations on the first 50 patients the author believes that extrapleural pneumothorax is particularly effective in bilateral collapse therapy. It has the advantage in that the healthy lower lobe remains adherent to the thoracic wall and diaphragm and thus obtains maximal ventilation. Extrapleural pneumothorax has a greater sphere of applicability than a thoracoplasty. The five rib thoracoplasty of Maurer most nearly approaches the efficacy of extrapleural pneumothorax.

Cirrhosis Caused by Schistosomiasis and Cirrhosis in General—Study of cirrhosis caused by *Schistosomum mansoni* makes it possible to review problems that concern cirrhosis in general. Jaffe agrees with Fiessinger that the anatomic basis is the same in all forms of cirrhosis. The author is convinced that this disease is systemic and that the hepatic lesions represent changes in one organ. Changes in the liver may be the only recognizable organic change. The spleen or other organs may

be involved at times. The causes of these differences are not known. Cirrhosis is essentially a parenchymal impairment of the liver. Primary damage of other parts of the liver have not been demonstrated. Changes in other tissues, such as the stellate cells, the lattice fibers and the connective tissue cells, are secondary to the parenchymal lesions. The degree and distribution of the parenchymal lesions determine the further changes. The same cause may produce various types of cirrhosis. It is of no importance whether the hepatic process is regarded as a chronic inflammation or as a transformation. The parenchymal lesion is primary and other lesions are elicited by it. A classification of cirrhosis on the basis of its anatomic appearance is not logical. Jaundice, as an accompanying symptom, is caused by the same parenchymal lesion as the cirrhosis, mechanical factors play a secondary role.

Neuwiler—p. 1217***Mechanism of Median Fracture of Neck of Femur** Treatment by Nailing According to Sven Johanssen O. Hauptli—p. 1220***Therapy of Herpes Zoster** K. Blum—p. 1223**Rocutgenologic Examination of Esophageal Spasm Can Lead to Error in Localization of Causal Lesion** F. Naville and R. Herrmann—p. 1224

Sven-Johanssen's Nailing in Median Fracture of Neck of Femur—Hauptli reports 43 osteosyntheses carried out for fractures of the neck of the femur between 1935 and 1941. During 1935 and 1936 Henschen's screw method was employed in 4 cases. The results were good in 3 and poor in 1. Eight patients were subjected to Sven-Johanssen's nailing without the guiding instrument, with poor results in half of the cases. Nailing according to Sven-Johanssen was done in 5 cases with the aid of the original guiding instrument of Valls. The results were excellent in 4 cases and poor in 1. During the years 1939 to 1941 Sven-Johanssen's method was employed in 26 cases with Ulrich's "infallible" modification of the directing instrument of Valls. The results were excellent in 22, satisfactory in 2 and poor in 2 cases.

Therapy of Herpes Zoster—The fact that sulfamylamide and a salt free diet produced favorable therapeutic results in postinfections and polyneuralgic conditions suggested to Blum that these measures, together with vitamins B₁ and C, be used early in the treatment of herpes zoster. In view of the virus origin of this disorder he suggests that the same therapeutic methods might be of value in other virus diseases, such as poliomyelitis, measles, acute epidemic encephalitis or venereal lymphogranuloma.

Acta Medica, Rio de Janeiro**10 157-180 (Dec) 1942 Partial Index*****Quinine and Other Antimalarial Drugs** Experiments S. B. Pessoa—p. 157**Tetanus Vaccination** J. Guilherme Lacorte—p. 172

Antimalarial Drugs—Pessoa experimented with camies previously inoculated with *Plasmodium cathemerium*. He found that the antimalarial effect of quinine hydrochloride is greater when the drug is administered intramuscularly than when it is given by mouth. Bolivian quinine sulfate is as efficacious as Java quinine. Potassium tannate injected intramuscularly has no plasmocidal properties. Potassium tartrovanadate has a plasmocidal effect only when it is administered in large doses. Such administration is dangerous because the therapeutic dose is close to the toxic dose. Sodium arsenate has no plasmocidal effect even in the highest tolerable doses.

Boletín de la Sociedad Cubana de Pediatría, Havana**15 105-152 (March) 1943 Partial Index*****Cerebral Tuberculosis in Disseminated Forms of Primary Tuberculosis in Infants** T. Valledor—p. 105

Cerebral Tuberculosis in Infants—The 4 infants observed by Valledor were living with tuberculous members of the family. They exhibited acute symptoms of disseminated primary tuberculosis. Disseminated miliary tuberculosis and one or more tuberculous nodules were found during a necropsy in the brain. In 2 cases development of miliary cerebral tubercles in primary miliary tuberculosis is the starting point for a latent tuberculo-

meningitis which manifests itself by symptoms of increased intracranial pressure, convulsions, acute headache exaggerated reflexes a positive MacEwen sign vomiting and coma. The course of the disease is rapidly fatal. The symptoms are those of a subacute hydrocephalus without increase in the size of the head. The spinal fluid is chemically and bacteriologically normal in the course of the disease, which develops with neither meningeal symptoms nor pathognomonic signs of a brain tumor.

*Problem of Vitamin A in Nutrition of Pregnant Women J Botella Llusia and J M Hernandez Arana —p 203

Glutathione in Blood During Nutritional Deficiencies—Cruz Añón and Rivero Fajardo show that the reduction of the glutathione values (thioamino acids) in the blood is the best proof of a diet which contains no animal proteins or has inadequate amounts of these substances which are rich in thio amino acids. They gained the impression that 'mal de Casal' is due to a meat deficiency and that hunger edema is due to universal deficiency. In Casal's disease the reduction in the glutathione content is considerable and in hunger edema it is even more severe.

Vitamin A in Pregnancy—Botella Llusia and Hernandez Arana tested the dark adaptation of 140 pregnant women. They detected impairment of night vision in 69 per cent of the pregnant women in whom the vitamin A content of the diet could not be controlled. Women with evident avitaminosis showed this defect in 95 per cent of the cases. Only 10 per cent of the pregnant women who received their food from the social aid organizations showed defects of the dark adaptation. This proves that the food provided by these organizations is adequate from this point of view. Since during pregnancy the organism partly loses its capacity to utilize carotene, it is advisable to administer preformed vitamin. Furthermore the nutritional requirements of the fetus increase the vitamin A requirements of the mother during pregnancy. Fats are of great importance in the diet of pregnant women because they are vehicles of vitamins and of carotene. The authors recommend that pregnant women should receive daily 4000 international units of vitamin A and 50 Gm of fat.

Neurodystonias—Jimenez Diaz and Lorente examined alcohol acetone soluble extracts of urines of 10 normal persons on different days of a patient with migraine during and after an attack of 2 patients with exophthalmic goiter with severe neurodystonia and of a patient with premenstrual hypertension at various times during the cycle. It was observed that the patients with exophthalmic goiter and the one with migraine eliminated during their crises a substance with an intense acetylcholine effect. The woman with the premenstrual hypertension had the same substance in the premenstrual urine whereas at other times her urine was free from it. The urines of the 10 healthy subjects were free from these effects. In the presence of a sympathetic neurosis as well as in migraine the substance is present in excessive quantities. The authors direct attention to the role of acetylcholine in the excitation of the sympathetic nervous system.

Pathogenesis of Hemoptysis H Basabe —p 253
Functional Reactions of Phenylethyl Sodium Method for Its Evaluation Rosa C D Messio de Carnevale Bonino —p 289

Therapy of Asphyxia in Newborn Infants—Schwarz and his collaborators advise the routine administration of oxygen carbon dioxide mixture by inhalation to all mothers who give birth under anesthesia, even if the latter is mild. The therapy is especially indicated when fetal respiration is not rapidly established. Oxygen-carbon dioxide mixture should be administered to the mother before sectioning the umbilical cord. Immediately after the inhalation of the oxygen, respiration of the mother improves and pulsation of the umbilical cord increases. The necessary requirements for obtaining results from the administration of oxygen carbon dioxide mixture are intact umbilical cord, an unimpaired center of respiration of the fetus upper respiratory tract free from mechanical obstruction and lungs of normal distensibility. The author's group of 36 mothers includes cases of spontaneous labor, application of forceps internal version and cesarean section. Good results were obtained in all cases but 3. Obstruction of the upper respiratory tract with mucus was the cause of failure of oxygen-carbon dioxide therapy in these cases. The infants were reanimated by aspiration of mucus and insufflation of the oxygen-carbon dioxide mixture.

Inguinoscrotal Hernia Containing Stomach—Jorge and his associates report the case of a man aged 66 with a double inguinoscrotal hernia. The one on the right side was enormous. Roentgenoscopy with an opaque meal revealed that parts of the stomach and intestine were present in the large hernial sac on the right side. The smaller hernia was operated on successfully and the wound healed by primary intention. The patient was instructed to return later for operation on the larger hernia. He was hospitalized in a state of prostration and dyspnea and died as the result of a bronchopulmonary process. The necropsy revealed the presence of the stomach in the hernial sac. The authors were able to find only 22 cases of this type in the literature. They stress the importance of a preoperative roentgenologic examination and point out that these giant hernias are compatible with a good general condition.

Diagnosis of Epilepsy by Means of Metrazol—Rois-miser points out that metrazol shock therapy led to the use of this substance in the differential diagnosis of epilepsy. He describes his observations on 56 subjects 38 of whom were epileptic and 18 were not. Of the first group 92.1 per cent responded with a typical crisis to the intravenous injection of 3 cc or less of a 10 per cent solution of pentamethylenetetrazol. The test was always begun with the injection of 1 cc. Two of the epileptic patients reacted with an attack to this dose. 3 reacted to 1.5 cc, 12 to 2 cc, 8 to 2.25 cc, 2 to 2.5 cc, 8 to 3 cc and 3 required more than 3 cc for the production of a crisis. The 18 subjects who were not epileptic all required more than 3 cc for the production of a convulsive attack.

Significance of Ascorbic Acid in Cerebrospinal Fluid from Point of View of Differential Diagnosis J Wirth —p 212
Therapeutic Short Wave Hyperthermia A von Teubner —p 211
Use of Mariand Frontal Sinus Powder in Surgery R Stein —p 221

Vitamin C Requirements—Kalk and Brühl report observations on a man who had lived on a diet free of vitamin C. He was hospitalized with all the symptoms of scurvy. The development of the scurvy had been favored by inadequate

nutrition, hard physical labor, an infection (otitis media) and achylia. In spite of a continued vitamin C free diet, bed rest alone counteracted the scurvy symptoms, although no vitamin C could as yet be demonstrated in the serum. Administration of small quantities of vitamin C (10 and 25 mg daily by mouth) increased the vitamin C content of the blood in spite of an existing achylia. The scurvy was practically cured at a time when the serum still contained extremely small amounts (0.3 mg per hundred cubic centimeters). With the daily administration of 25 mg on a diet that was practically free from vitamin C and in the presence of "normal" vitamin C values in the blood a good working capacity and complete freedom from symptoms could be maintained. This status continued even after the vitamin content sank to low levels following cessation of the administration of vitamin C. The authors stress that the development of scurvy is rare even in a population with a low vitamin C intake. Only 5 cases of scurvy were encountered in about 16,000 patients. This rarity shows that vitamin C deficiency alone is not sufficient for the development of scurvy. Other factors detrimental to the vitality must be added, such as lack of sleep, infections, hard physical labor and starvation. A daily quantity of 25 mg of ascorbic acid is adequate to prevent hypovitaminotic conditions.

- Action of Water Soluble Desoxycorticosterone on Carbohydrate Metabolism O. Göbell and H. J. Benkner—p. 17

Local Application of Sulfonamides in Soil Contaminated Wounds—Schreus investigated the efficacy of various sulfonamides when introduced locally into soil contaminated crushed muscles (intensified Friedrich's experiment). He found that the efficacy in suppressing the development of gas gangrene depended on the quantity of the drug introduced as well as on the time which had elapsed between the infliction of the wound and the administration. When the drug was applied to the wound before six hours had elapsed, comparatively small quantities were adequate to prevent gas gangrene, but when administration took place between six and eight hours larger quantities were necessary. Neither the pure sulfonamides nor their combinations with one another or with boric acid or methenamine were capable of preventing the death of the animals from gas gangrene if introduction into the wound was delayed more than nine hours. The sulfonamides act on the gas gangrene organisms locally as well as by absorption. Since there is no danger of injury to the tissues, the author recommends the combined local and systemic administration.

- Thymotropic Hormone of Anterior Lobe of Hypophysis and Thymus Hormone W. Biehler, G. Hanisch and H. Wollschütt—p. 63

Blood Sodium Chloride and Diastase in Diabetes Mellitus—Dörle says that blood diastase varies considerably in the blood of normal persons. The fall in blood diastase below 80 mg per hundred cubic centimeters is abnormal and occurs in severe diabetes associated with ketonuria, inflammatory complications, grip infections, cachexia and severe anemia. The decline in diastase values parallels a fall in blood sodium chloride in many instances and an increase in blood sugar in

diabetic patients. But this parallelism is not a real one. Isolated disturbances of these substances are possible. The fall of sodium chloride and diastase of the blood does not depend on a certain type of metabolic disorder or on a special kind of organic disease. The fall is secondary to disturbances of nutrition. Sodium chloride blood content, blood sugar and diastase are related to the metabolism. High blood sugar values and low sodium chloride and diastase content may parallel other disturbances, as in severe acidosis of diabetes. Diastase seems to be the most labile element of all. It is readily lowered by a general or toxic disturbance of nutrition.

Riboflavin in Carcinoma—Leemann determined the riboflavin content of tumor tissue and of tissues of normal organs. The concentration of riboflavin in carcinomatous tissue is higher than in the matrix and in the normal tissue. On the contrary, the concentration of riboflavin in tissues of normal organs was lower than that of the average values present in normal tissues of persons not affected with a malignant tumor. The increased demand of the tumor for vitamin B₂ is responsible for the impoverishment of riboflavin in other organs, which in turn results in a reduction of the excretion. While persons not suffering from carcinoma excreted within two days 70 per cent of riboflavin administered to them parenterally, persons with a tumor did not excrete more after parenteral administration of riboflavin.

- *Local Causes of Postoperative Development of Jejunal Ulcer E. Sipos—p. 130
- Intestinal Occlusion by Gallstones D. Klimko and L. Fedele-Findelsen—p. 145

Local Causes of Postoperative Jejunal Ulcer—Sipos believes that postoperative jejunal ulcers are largely preventable by careful attention to the local conditions during the first operation. The fact that they develop only after a gastrojejunostomy indicates that the new position is a cause. The fact that not every gastrojejunostomy is followed by jejunal ulcer suggests that other factors play a part. The author differentiates two groups of causes: (1) those that intensify the harmful effects on the intestinal mucosa and (2) those which reduce the resistance. It is not the absolute severity of a single factor but the relationship of the two groups of factors that is decisive. Case histories demonstrate that one of the local causes of postoperative jejunal ulcer is the improper operation such as a gastroenterostomy for a perforation or enteroanastomosis according to Brown and Roux. The patient should be prepared for operation by blood replacement and by normalization of the mineral and water balance and of the vitamin C deficit. In case of prepyloric ulcer the vicious circle of stasis, prolonged secretion, inflamed mucosa, muscle spasm and atony must be interrupted. Systematic evacuation of the stomach relieves the spasticity of the musculature, and irrigation of the mucosa reduces inflammation. Gastrojejunostomy should not be performed for a perforation. Only that operation can be considered as optimal which eliminates overburdening of the mucosa, preserves intestinal resistance and produces, as far as possible, normal physiologic conditions for the gastro-intestinal function. In case of a resectable ulcer, removal of the distal half of the stomach is usually adequate, two third and four fifth resections are inadvisable. For a palliative resection it is advisable to remove all the antral mucosa and resect more extensively. A relatively small anastomotic opening is desirable in order that the stomach may complete its digestive action, exhaust the effect of the gastric juice and prevent bile regurgitation. That position of the stoma will be the most advantageous which will permit evacuation of the stomach contents into the descending loop. Since inadequate blood supply probably favors the development of ulcers, the most careful handling of the tissues is essential. A fine absorbable suture material should be used. Roux's or Brown's enteroanastomosis should never be employed. It is advisable to avoid spinal paravertebral or splanchnic anesthetics, with a careful surgical technic, infiltration anesthesia of the abdominal walls is adequate.

Book Notices

Textbook of Biochemistry By Benjamin Harrow Ph.D. Professor of Chemistry City College of the City of New York Third edition Cloth Price \$1.15 Pp 337 with 115 illustrations Philadelphia & London W. B. Saunders Company 1913

The last few years have witnessed vast progress in the field of biochemistry. Considerable advancement has been made in the field of the intermediate metabolism of carbohydrates, fats and protein and in the employment of isotopes as tracer elements for complicated or little understood biologic mechanisms. The last years have also witnessed great developments in the fields of enzymes, vitamins and hormones in the field of biologic oxidations and in our knowledge concerning the breakdown and synthesis of glycogen through systems of enzymes and coenzymes. The very fertile fields of viruses, of bacteriostatic or bactericidal compounds such as gramicidin and penicillin of immunochemistry and of chemotherapy have also been energetically explored. Medical practice has derived its share of profit from the applications of the newer knowledge of biochemistry to problems of diagnosis, prognosis and treatment.

The rapid advances in biochemistry call for considerable revision in any edition of biochemistry more than three years off the press. The first edition of Harrow's Textbook of Biochemistry was published in 1938, the second in 1940 and the third this year. All the important late findings in the biochemical field have been incorporated in the new edition. In the unfortunate attempt, however, on the part of the publishers to keep down the size of a book in the most rapidly expanding field of science, the newer topics for the greater part have been treated with the brevity of a dictionary and do not receive the adequate treatment befitting a modern textbook of biochemistry that lays claim to being up to date.

Nevertheless, Harrow's new edition has many excellent features. The text reads well. The language is simple and clear and to the point. The graphs and pictorial illustrations are exceptionally well chosen. Among the illustrations are photographs of animals and human beings with various mineral vitamin or hormone deficiencies, photographs of enzymes in crystalline form, such as urease, pepsin, trypsin and chymotrypsin, and photomicrographs of molecules of tobacco mosaic virus made by means of the electron microscope with a magnification of 34,000 to 37,000.

The book literally abounds with graphic formulas and complicated chemical equations. The chemical synthesis of vitamin B₁₂ and of androsterone is given all the intermediate steps being represented by formulas. The various reactions involved impart to the student an insight into the problems concerned with the synthesis of an important biochemical compound. Each chapter ends with a page or two of references unique in that they differ from an ordinary list of authors' titles and journals. They aim to guide the student to the best literature—books, reviews and individual articles—on a particular topic.

Whenever the author goes into a subject at some length he proves to be at his best and succeeds in giving to the student a comprehensive view of the subject. It is for this reason that the chapters on carbohydrates, on proteins, on enzymes, on vitamins, on hormones, on detoxication, on the chemistry of respiration on biologic oxidations and on the metabolism of carbohydrates which includes the breakdown and synthesis of glycogen are the best in the book. If this book is to be kept confined to a limited number of pages, it is suggested that in future editions chapter 7, on foods, could be well omitted since the material included really belongs to a book on dietetics or nutrition and chapter 20 on energy metabolism could well be relegated to a textbook of physiology.

The book on the whole is valuable to a college or university student, undergraduate or graduate, who is desirous of acquainting himself with the subject matter of biochemistry. It covers the usual requirements of courses in this subject offered to students in agriculture, in nutrition and to college students in general. The volume also constitutes a valuable textbook for

the student of medicine or for the progressive physician for the emphasis it lays on the purely chemical side of biologic chemistry. Its usefulness to the medical student or to the physician, however, would be greatly enhanced had the subject matter been treated more liberally from a biologic point of view and applied to or brought into direct relation with the chemical problems involved in disease.

Intensive Rural Hygiene Work in the Netherlands East Indies By J. L. Hydriek M.D. With an Introduction by Professor J. Snapper. This Study has been Reprinted with Slight Revisions from a Report of the Public Health Service of the Netherlands East Indies. Published in 1917. It is Submitted as a Document for the Eighth Conference of the Institute of Pacific Relations, December 1932. Booklets of the Netherlands Information Bureau No. 7. Paper. Pp. 83 with illustrations. New York: Netherlands Information Bureau 1942.

Although this booklet purports only to describe the program of public health in the rural parts of the Netherlands East Indies especially in Java, its scope is actually far broader. The author's account of the development of the program serves as a basis for a discussion of the general principles that might well apply to the conduct of public health work in any part of the world. While the author does not presume to do more than present the philosophy underlying the program in the East Indies, he has actually written a treatise that merits careful examination by all students of public health and especially by those engaged in rural areas. His underlying tenet is that lasting progress can be made no faster than the public is educated to appreciate and to want improved conditions of sanitation and health. Enforcement of laws that are neither understood nor supported and the indiscriminate rendering of health services to an unappreciative public are rejected as of no permanent value even though he concedes that they may yield dramatic yet fleeting results. The author supports the thesis that education, though slower, yields more lasting and hence greater return. Special emphasis is placed on the personal type of education rather than the dramatic health propaganda so commonly encountered. The author stresses the desirability of completely separating preventive from curative aspects of public medical service. Though somewhat rambling in style and repetitious in places, the pamphlet is one that should be read by all interested in the promotion of public health whether in the Netherlands East Indies or in the United States.

Manual of Veterinary Bacteriology By Raymond A. Kelsey D.V.M. & M. Ph.D. Brigadier General United States Army Chief Veterinary Division Surgeon General's Office War Department Washington D.C. and Harry W. Schoening V.M.D. Chief Pathological Division Bureau of Animal Industry U.S. Department of Agriculture Washington D.C. Fourth edition. Cloth. Price \$6.50. Pp. 719 with 94 illustrations. Baltimore: Williams & Wilkins Company 1943.

The appearance of this book is timely. It arrives at a moment when concerted action is being taken to guard the nation's food poundage against infections of food producing animals. Among those who labor in the field of animal medicine the four revisions in but a few years are accounted for by the reliability of their text plus the constant development of new knowledge of animal diseases control which the veterinary service must use to accomplish its purpose. To that end the senior author obviously overwhelmed by wartime duties, obtained the aid of Schoening and his co-workers of the Animal Disease Research Station at Beltsville Md. That their vast experiences on the farms, ranches and abattoirs throughout the United States complement the material of previous issue is self evident and universally admitted in the livestock sanitary circle. In this place it ought to be sufficient to say that this book covers all the main bacterial, protozoal and virus infections to which the domestic animals of the United States are exposed directly or indirectly. Although the subjects are arranged according to the familiar pattern the material is more of a pathologic than of a bacteriologic character. Since the objective is the mastery of disease the details of prophylaxis, therapeutics and hygiene are not slighted. Physicians should find interest in the chapters on tuberculosis, brucellosis, rabies, the crebricidalities and the salmonellosis and the ruthless war veterinarians wage against them to perpetuate the good name of the United States as a food producing country.

Aids to Tropical Medicine By I C Broom M.D., Bacteriologist to the Wellcome Bureau of Scientific Research, London Fourth edition Cloth Price, \$1.75 Pp 203, with 30 Illustrations Baltimore William Wood & Company, London Baltimore, Tindall & Cox, 1912

In 1908 the late Gilbert E Brooke, then port health officer of Singapore, brought out the "Aids to Tropical Medicine" as a part of the students' aids series. Three editions were published under the author's direction, the last in 1927. Since that date the field of tropical medicine has seen such changes that a new edition was in order to keep the volume in step with recent developments. The current volume by Dr Broom fills that need. The author has attempted wherever possible to preserve the original text and form but has had to make extensive revisions and in many instances to rewrite entire sections. Dr Broom has wisely chosen to depart from the earlier alphabetical grouping of diseases, which had nothing in its favor other than ease of reference, and has elected to group diseases on an etiologic basis. The latter method leads to better understanding on the part of the student. Each disease is discussed under a logical and fairly standard pattern including definition, geographic distribution, history, etiology, pathology, symptoms, diagnosis, treatment and prophylaxis. More attention is given the latter aspect than in previous editions. Although the total length of the volume has not been increased, the author has been able to include a section on rickettsial diseases. The volume is not intended as a comprehensive textbook of tropical medicine but rather, as its name implies, as a study aid. In this it has richly fulfilled the purpose for which it was designed.

Diagnóstico de los tumores abdominales. Oncoquiliagnosis. Tomos I y II. Por Pablo L. Mirizzi profesor titular de Clínica quirúrgica de la Facultad de Ciencias Médicas de Córdoba. Cloth Pp 670, with 192 Illustrations, Pp 671-1289, with 189 Illustrations. Buenos Aires Librería 'El Ateneo,' 1911, 1912.

This work concerns itself mainly with diagnosis of abdominal tumors, to which the author refers as "oncoquiliagnosis." In volume I a general study of the abdomen as to its physical characteristics, history and physical examinations of the patient, which embraces laboratory methods, are presented. The specialized part comprises diagnostic points concerned with internal and external hernias, tumors of the peritoneum, the intestinal tract and pathologic entities of the liver. The entire presentation, which is thorough, deals with the diagnosis and differential diagnosis of abdominal tumors. The author stresses the necessity of resort to all available means to arrive at a correct preoperative diagnosis wherever possible. In volume II the author discusses diagnostic features of the gallbladder, spleen, large omentum, kidneys, pancreas, bladder and sympathetic nervous system, the material gathered here is as thorough as that in the first volume. In the chapter on the biliary passages a great deal of information is garnered. It will be recalled that it was the author who popularized cholangiography. The chapter on retroperitoneal and kidney tumors is particularly well presented. At the end of each chapter there is a review of the literature. The illustrations are clear, the paper and binding excellent. The work concludes with an author's index and a comprehensive index of subject matter. Students and others who read Spanish will find Mirizzi's book of value.

Blood Groups and Transfusion By Alexander S Wiener A.B. M.D. Serologist and Bacteriologist in the Office of the Chief Medical Examiner of New York City Third edition Cloth Price, \$7.50 Pp 438 with 69 Illustrations Springfield, Illinois & Baltimore Charles C Thomas, 1943

This book has been eminently successful since it was first published in 1935. The rapid growth of our knowledge of blood groups and the widening field of their application in medicine and surgery is manifested by the increase from 220 pages in the first edition to 306 in the second and 438 in the present, with a corresponding rise in the number of tables and illustrations. The book covers the theoretical background so necessary for the understanding of this intricate subject, the technical procedures, the transfusion of fresh and stored blood, of plasma and serum and the medicolegal applications in disputed parentage and in examination of stains. The recently discovered Rh factor (the author of the book was the co-discoverer) and its applications to the prevention and understanding of blood transfusion reactions (this too a discovery by Wiener) and to the pathogenesis of fetal erythroblastosis are treated clearly and exhaustively in a new chapter. Another

new chapter is devoted to recent developments in the use of stored blood and blood substitutes. The presentation is lucid. Small print permits one to skip details less interesting to the nonspecialist. The index is well organized. The general practitioner and every physician regardless of specialty will find in this monograph all that is worth knowing in the field it covers.

A History of Nursing By Deborah MacLurg Jensen, R.N., M.A. Instructor in Sociology and Social Problems at Schools of Nursing of St. Louis City Hospital and St. Luke's Hospital St. Louis. Cloth Price \$2.75 Pp 310, with Illustrations St. Louis C.V. Mosby Company 1913

Modern medicine and modern nursing are closely associated in their historical growth and development as they are in practice. Emphasizing this theme, Mrs. Jensen has prepared an excellent history of nursing against a background of social and economic progress and medical advance. The history of nursing in this country and abroad, the part played by Florence Nightingale and the great nurses who came after her, and the roles of the Red Cross and the Army in the development of modern nursing are all adequately and interestingly discussed. This book should make medical men proud of the parallel advances in their sister profession.

Fractures and Dislocations By Various Authors Edited by Sir Humphry Rolleston Bt. G.C.V.O., M.D., and Alan Moncreff M.D., F.R.C.P. Cloth Price 7s 6d Pp 104, with 25 Illustrations London "The Practitioner" in conjunction with Eyre & Spottiswoode, 1943

This small book is full of good material. It is composed of a six article symposium which appeared in the British publication *Practitioner* for June 1940 and two additional articles. Each of the eight authors is a national authority, five are known internationally. The handy booklet presents the latest thoughts of recognized experts on highly specialized subjects. Illustrations are sparse. The index helps the busy practitioner in an emergency. The subjects covered are "The Diagnosis and Treatment of Fractures and Dislocations of the Pelvis and Hip Joint," "Common Fractures and Dislocations of the Knee and Long Bones of the Lower Limb," "Fracture-Dislocations of the Ankle Joint," "Common Fractures and Dislocations of the Clavicle and Shoulder Joint," "Fractures and Dislocations at the Elbow," "Fractures and Dislocations of the Wrist and Hand," "Head Injuries" and "The Treatment of Spinal Injuries."

Illustrations of Surgical Treatment. Instruments and Appliances By Eric L. Farquhaison, M.D. F.R.C.S.E. Major R.A.M.C. With a foreword by Sir John Fraser M.C. M.D., Ch.M. Regius Professor of Clinical Surgery University of Edinburgh Second edition. Fabrikoid Price \$7 Pp 392 with 380 Illustrations Baltimore William Wood & Company, 1942

This contains a wealth of useful information presented in a practical and readily understood manner. The illustrations are excellent and well chosen, the text is brief yet broad enough to cover the subjects, which are comprehensively discussed. By the use of photographs and drawings the author has described methods of treatment and the types of apparatus employed in an ingenious manner. This book should be of especial value at the present time when a global war is in progress, but every physician will find information of pertinent value whether he is in the armed forces or in civilian practice. Fractures and orthopedic problems, intravenous therapy and injuries to the extremities are considered, and the book contains an extensive appendix showing surgical instruments and appliances.

Dictionary of Bio Chemistry and Related Subjects Editor in Chief William Marias Mallison Professor of Bio Chemistry at the Polytechnic Institute of Brooklyn Cloth Price, \$7.50 Pp 579 New York Philosophical Library 1943

Although dictionaries have formed an integral part of scientific libraries for years, they often are inadequate to meet the needs in special fields. The Dictionary of Bio-Chemistry is "designed for readers of biochemical literature who might want the definitions of terms used more than a decade ago as well as of terms just coined." The idea for such a dictionary is commendable, it is unfortunate that the book falls short of expectations. Many definitions are too brief to be of much value, a few unnecessarily long, some misleading. Undoubtedly many of these faults will be corrected before the next issue appears. The usefulness of the book then will be vindicated.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

STERILITY OF SULFONAMIDE POWDERS

To the Editor—In reply to an inquiry on sterilization of sulfathiazole powder in Queries and Minor Notes in The Journal Oct. 4, 1942, page 1221, it is stated that it is possible to sterilize sulfanilamide, sulfapyridine, sulfathiazole or sulfadiazine by heating at 140 C. for four hours. It is also possible to autoclave small amounts of drug in flasks at 15 pounds pressure for twenty minutes. This will sterilize the powder, but occasionally there is a tendency for the powder which has been sterilized in this fashion to cake in the flask. Would you advise if it is intended that the flask in the autoclave be open or closed? If the flask is open the contents will be exposed to moist heat. If the flask is closed however the moist heat will be excluded and the material in the flask will be subjected to a dry heat equivalent to the temperature of the moist heat outside it. As it is also stated that 140 C. for four hours is necessary to sterilize the powder is it possible that steam heat for twenty minutes could sterilize the powder in a closed container in the same way that it would in an open container when the contents of the flask are exposed directly to the moist heat of the autoclave? The latest supplement to New and Nonofficial Remedies, 1942, includes Sulfanilamide (Sterile Crystalline) 5 gram shaker type package by Hynson, Westcott & Dunning, Inc., Baltimore. Other pharmaceutical houses are also offering for sale similar types of packages. These vary in minor details but all carry a common claim in that they have the word "sterile" prominently displayed on the package. There can be no question that the term "sterile" is intended in an absolute sense, that is free from all bacteria, spores or other organisms. Assuming that the drug in these envelopes is sterile at the time of manufacture, is it possible for the sterility to be preserved indefinitely in this type of container which can be demonstrated to breathe air evidently through the folds of the paper? If however the air is not breathed through the folds of the paper but through the paper itself, which is unlikely, can paper of this type be considered capable of filtering bacteria? What effect would excessive atmospheric moisture have on the permeability of bacteria through the paper?

J. M. Bourque, M.D., Sorel, Quebec, Canada

ANSWER—First sulfonamide powders may not be sterilized in the autoclave if they are in tightly closed containers. The steam must be able to reach the powder and this is liable to cause caking. If the powder is sterilized by dry heat in paper envelopes of good quality and well sealed, especially if a double envelop is used, there is little likelihood that they will become contaminated if kept dry and with ordinarily careful handling, as when kept in original cartons or in the first aid kits of soldiers. For the Army and for the medical trade the sulfanilamide powder is packaged in double paper envelopes, six or a dozen such envelopes sold in cardboard cartons wrapped in cellophane. Many such individual envelop packages (not in cartons) have been placed in the dust bags of vacuum cleaners in use in hotels and have been examined after six months of such abuse. They were found thoroughly black with dust and about 10 per cent of them were found contaminated. For the Navy the powder is packaged in single paper envelopes and each of these is enclosed in a sealed cellophane envelop. The Navy prefers this package with a view to keeping out moisture. There is little likelihood of contamination through dry unbroken paper of fair quality but molds and possibly bacteria might grow through moist paper, even as in a humid atmosphere during several days.

RINGWORM ABOUT PERINEUM—DANGER OF X RAYS

To the Editor—What can you tell me about the treatment of a tinea or fungus infection in a man around the scrotum and perineum? Would ultraviolet treatment clear up the infection? He has tried ointments with only temporary success. He has tried x-rays but is afraid of being sterilized.

G. E. Ramseyer, M.D., Plainwell, Mich.

ANSWER—The greatest caution should be exercised in exposing the perineum and scrotum to x-rays because of the great sensitivity of the testes to their action. In the present instance x-rays should not be used at all, even though they may be effective against eczematoid ringworm. Eczematoid states of the scrotum are often exceedingly stubborn to treatment of diverse sorts. Ultraviolet rays in suberythema doses may be used but are not especially effective. Care should be given not to increase the dermatitis by excessive dosage because of the aggravating factors of heat and friction at the parts.

The diagnosis of ringworm infection should be checked by searching for fungi by direct and cultural methods. These

infecting elements are not always found at the first trial. Tinea cruris is most often an extension process of eczematoid ringworm from the feet and toes. It found, here too, the therapy must be directed to include these primary sites. Failure to take this precaution accounts for some failures of treatment given to the scrotal and crural areas alone. Less often than the feet and toes, the hands and fingers too are involved.

Local therapy alone is almost always sufficient to achieve a successful conclusion to these infections. If the dermatitis is acute in degree, wet dressings give the greatest relief. For this purpose solution of aluminum subacetate 1 part in 10 to 15 parts of water serves well. When the acuity or the inflammation has subsided the wet dressings may be replaced with lotions at the genitocrural area. Calamine lotion may be fortified with a tar such as coal tar solution from 3 to 10 per cent or resorcinol 1 to 5 per cent concentration. A useful measure for the toes is to separate them by pledgets or cotton changed several times a day to keep the parts dry. Helpful too is a dusting powder consisting of 5 to 10 per cent sodium thiosulfate, 10 per cent boric acid and 3 per cent salicylic acid in equal parts of zinc stearate and talcum. When the chronic stage has been reached ointments are the most useful. Whitfield's ointment mixed with three times the amount of petrolatum or the more modern cholesterinized or water miscible bases is often useful on the feet and on the perineum. While the full strength Whitfield ointment can be finally reached, this is ordinarily much too strong for the scrotum and nearby regions. Some people can stand it, but it is bold treatment for the majority. Instead of Whitfield's ointment various parasitocides may be put in grease bases and used in the same way. Some of these are resorcinol 1 to 10 per cent, ammoniated mercury 1 to 10 per cent, sulfur 1 to 5 per cent, beta-naphthol 1 to 10 per cent, chrysarobin 0.1 to 10 per cent, essential oils such as thymol 0.1 to 2 per cent and cinnamon oil 0.1 to 2 per cent. In general it is better to begin with the weaker concentrations and graduate to the stronger as the patient's tolerance permits. The palms and soles will usually bear considerably more aggressive treatment than the parts about the perineum. Water and soap should be avoided but oils including mineral oil may be used as cleansing agents. Boric acid solution too is useful for the same purpose. Ordinary care will serve as prophylaxis against the spread of the infection to others in the family, infected persons should not frequent public baths or swimming pools.

EFFECT OF PSYCHE ON MENSTRUATION AND OVULATION

To the Editor—It is a generally accepted fact that the menstrual flow usually commences fourteen days after ovulation, equally accepted is the fact that more or less profound psychic disturbance may suppress menstruation. Is this type of amenorrhea dependent on a failure of ovulation? In other words in an ordinary regular twenty-eight day cycle in which a delay of six days in the appearance of the period has occurred because of nervous anxiety and assuming that all suppressing influences are absent, when may the next menstrual flow be expected? Will pronounced psychic influences occurring in the latter third of a twenty-eight day cycle suppress the flow?

M. D. Illinois

ANSWER—The effect of the psyche on the menses is by no means clear but there is no doubt whatever that there is a distinct connection between the psyche and menstruation. Among the numerous examples are the cases of pseudocyesis or false pregnancy in which the prolonged amenorrhea and other symptoms are associated with an intense desire for children. Other examples are those of amenorrhea in unmarried girls who worry that they may be pregnant. In animals the connection between the nervous system and ovulation has been proved. In the rabbit, ferret, squirrel and cat, ovulation and luteinization never occur without the nervous excitation of mating. In fact, simple traction of the vulva or artificial stimulation of the cervix produces ovulation even where the ovaries are removed from their normal location and implanted elsewhere in the body. It has been shown that the ovulation and luteinization in these cases result from reflex stimulation of the anterior hypophysis. Therefore in spite of the fact that the anterior pituitary gland is considered the regulator of the menstrual cycle, there is a center which in turn has a controlling effect on the pituitary gland. In many women the menses continue with their usual degree of regularity in spite of mental upheavals whereas in others a slight psychic shock upsets the menstrual schedule. The most likely explanation for disruption of the menstrual cycle is that the psychic disturbance affects the gonadotropic function of the pituitary gland which in turn brings about a change in the time of ovulation either by stimulating it prematurely or by suppressing it temporarily. However there are instances in which this explanation cannot hold, as in cases of bleeding which occurs almost simultaneously with the psychic trauma and the sudden stoppage of the menstrual bleeding due to fright or other reason.

There is no certainty about the time of occurrence of the menstrual flow following the delayed menses. In some instances the next flow will begin when it would have done so had the delay not taken place, but in most cases a new cycle is begun with the delayed menses. Strong psychic influences occurring in the latter third of a twenty-eight day cycle can suppress a flow, but this occurrence certainly is not inevitable.

VAGINAL SMEAR AS GUIDE TO ESTROGENIC THERAPY

To the Editor—Kindly tell me the present consensus on the use of vaginal smears for the evaluation of correct dosage of estrogenic hormones. In spite of the appearance of an article recently in a circular from a pharmaceutical company indicating that such examinations are reliable, it would seem from the study of the literature that opinions are rather divided.

Lawrence Parsons, M.D., Reno, Nev.

ANSWER—A study of the vaginal smear is a fairly good indication of estrogenic activity and serves as a guide to therapy in patients undergoing treatment with estrogenic substances. This is brought out by R. B. Greenblatt (*J. M. I. Georgia* 30:297 [July] 1941), who showed that vaginal smears may serve to indicate the degree of efficiency of estrogenic therapy. Geist and Salmon (*Am. J. Obst. & Gynec.* 41:29 [Jan.] 1941) and many others have shown that the administration of estrogens to women demonstrating deficiency of these hormones will definitely produce regenerative changes in the vaginal mucosa if adequate dosage is employed, thus making a basis of therapy of smears vaginitis by use of estrogenic substances.

Another place in which the vaginal smear is of value in estimating the efficacy of estrogenic therapy is in cases of gonococcal vaginitis in children. Such therapy produces a mature type of mucosa and the presence of such a mucosa means that the gonococci have disappeared.

In the presence of infection or chronic irritation, however, the evaluation of the vaginal smear may be upset and one must be on guard to recognize such an infection when present and to interpret the smear findings in these instances accordingly.

MOLD INFECTIONS OF VAGINA AND CONTRACEPTIVE JELLIES

To the Editor—Since molds are used in the manufacture of citric and lactic acids, could the gels containing either when used in contraceptive technique cause a low grade urethritis in a person whose membranes are allergic to molds? The question came to mind when a young married woman came to my office with a slight irritation and a low fever, there were myriads of pus cells and many molds in a microscopic examination of the urine. From the history it appeared that the beginning symptoms were mild and coincided with the first use of the gel. There was a slight exacerbation following work by an ophthalmologist for a recurring conjunctivitis.

M.D., Georgia

ANSWER—Contraceptive jellies are, for the most part, made from carbohydrate materials which many molds find nutrient. For this reason nonirritant materials are added in low concentration to prevent mold growth. Since the contacts between these and any mold which may be picked up in the process of manufacture is prolonged, the concentration of the mold destroying ingredient need not be high. It seems improbable that molds which might be picked up in the course of the manufacturing processes could survive this prolonged contact.

Mold infections of the urethra and bladder do occur and could, of course, be caused by an infection brought to the urethral orifice by a contraceptive jelly. In view of the almost invariable presence of mold destroying substances in the formulas from which contraceptive materials are prepared, however, it would seem that these would be extremely rare and that other contacts might be equally apt to carry in air borne spores.

SIGNIFICANCE OF DIPHTHEROID ORGANISMS IN BLOOD CULTURE

To the Editor—A man aged 60 with pyrexia of three months' duration and symptoms suggestive of bacteremia has had twelve blood cultures over the period of observation (three months). All but four have been negative. From these a diphtheroid organism has been recovered. One of two bacteriologists who have made the cultures say they are of significance. The other says they are not. Which is the correct position?

Wyndham B. Blanton, M.D., Richmond, Va.

ANSWER—If diphtheroid organisms are found in the blood of the same patient on four of twelve different occasions it is important that these organisms be studied to determine whether they are the same culturally and antigenically. Their pathogenicity for animals should also be alike. If errors in technique are ruled out and the organisms are found to be identical, they are of significance.

EXPOSURE TO CARBON TETRACHLORIDE COMPOUND

To the Editor—What are the possible poisonous effects from a duplicator roller cleaner consisting of half carbon tetrachloride with half Blankrola? It is claimed that absorption of this substance occurs through the hands or lungs and that it harms the bronchi and nerves.

M.D., Kentucky

ANSWER—According to Franco, Blankrola has been found to contain carbon tetrachloride in addition to a normal cleaning solvent. The toxicity of carbon tetrachloride in cleaning solutions is still not as well known as it should be in view of the seriousness and extensiveness of poisoning which can result from the inhalation or absorption of this substance. According to Davis the following symptoms may be caused by exposure to carbon tetrachloride fumes: slight headache, nausea (in many cases this becomes severe and lasts for several days), nervousness, mental confusion, loss of weight, dry dermatitis, secondary anemia, slight jaundice, chronic spasms of muscles, necrosis of the liver, acidosis, phosphaturia and irritative nephritis, loss of consciousness, coma and death, and visual disturbances such as blurred vision, color confusion and disturbance of near vision.

INHALATION OF NITROUS OXIDE FUMES

To the Editor—Will you kindly advise the best treatment for inhalation of nitrous oxide fumes—the fumes from the burning of photographic films?

Elmer W. Clarke, M.D., Norton, Mass.

ANSWER—In the March 1943 issue (12:128) of *Industrial Medicine* appears an extended article by Fleming dealing with the handling of patients gassed with nitrous fumes. Emphasis is placed on the pathology, diagnosis and treatment of such cases. There are two periods of anoxia following nitrous oxide gassing, assuming that the quantity of exposure is sufficient to have brought about injury. The first occurs early after exposure and apparently is attributable to a spasm of the terminal bronchioles. The second arises with the development of significant pulmonary edema. Emphasis is placed on the necessity for absolute rest and oxygen inhalation, if edema appears, 25 per cent solution of dextrose-saline solution should be introduced intravenously. If cyanosis and venous engorgement arise, venesection may be indicated but under some circumstances is contraindicated. It appears that no benefit derives from such drugs as morphine, barbiturates, nikethamide, epinephrine or the sulfonamide compounds, although the latter may be useful in case pneumonia ensues. The article mentioned furnishes extensive information and a short bibliography.

HYPOSENSITIZATION TO GRAIN DUST

To the Editor—A woman aged 31 is troubled greatly with asthma. Her husband operates a grain and feed mill, and several patch tests done with grain taken from his clothes show quite a positive result. I should like to know where I can have a sample of this grain made into a solution for desensitizing the patient. She has been given injections with grain solutions obtained from some allergen manufacturing company, and I wonder if using her own grain would be better, because she obtained no benefit from the injections.

Henry Friedman, M.D., Granville, N. Y.

ANSWER—In the last few years a number of papers have been published regarding the relationship of dust from grain and feed mills to asthma and rhinitis, and there is no doubt whatever that these dusts are frequent causes of allergic symptoms in those who are exposed. Good results too have been reported by hyposensitization, beginning with small doses of a weak solution of the proper dust extracts and increasing the dosage and strength up to the patient's tolerance. Better results as a rule are obtained with extracts made from dust obtained from the patient's place of employment. The dust can be extracted by any pharmaceutical house which specializes in allergic products or by any allergist who is properly equipped to do this. In either case, instructions as to dosage should be furnished with the extract.

The husband should by all means change his clothes, and if it he does not bring the mill dust home.

A STATISTICAL STUDY OF MINOR INDUSTRIAL BURNS

ROY D. McCLURE, M.D.
AND
CONRAD R. LAM, M.D.
DETROIT

Much has been written on the subject of burns during the past decade and a half and a large amount of laboratory and clinical investigation has been carried out. Nevertheless at the present time there is no method of local treatment which is accepted as standard by those who take care of these injuries. However it can be said that for the more serious or hospitalized cases some unanimity of opinion is beginning to be discernible. For example, there are few proponents of the coagulation methods which make use of such chemicals as tannic acid.

It has been suspected that there has been considerably less standardization of the treatment of minor burns, such as are frequently seen in industrial plants. It was decided that it would be of considerable interest to know how these small injuries are being cared for and approximately what results are being obtained. The following industrial surgeons were consulted and readily agreed to cooperate in a survey of minor burn treatment in the plants of the three large automobile companies now engaged 100 per cent in the stupendous production of war material. Dr. C. D. Selby, consultant, General Motors Corporation, Dr. John J. Prendergast, medical director Chrysler Corporation, and Dr. Harley Krieger, chief surgeon of the Ford Motor Company. This survey thus represents the burns occurring in a group of approximately 250,000 employees.

A supply of forms for the making of weekly reports was sent to the medical departments of a large number of plants. The heading on this form is shown in the accompanying tabulation.

The plant surgeons were instructed not to report a case until treatment was finished and the employee had been discharged from treatment. The response to the questionnaire was gratifying. Of 7,608 cases reported, 5,609 were tabulated for study. The other cases were not included because of insufficient data.

The most striking fact brought out in the study was that no less than eighty-four different substances were used in the treatment of the burns in this series.¹ Many of the remedies were proprietary preparations, some of which were adequately described on the labels or adver-

tising literature, others were described ambiguously. There were several different brands of certain more or less standard substances, such as tannic acid jelly and vitamin ointments. Each brand was tabulated separately, which helped to swell the list of different materials to the high figure just mentioned. It would not be desirable in this paper to mention by name all the substances studied but rather an attempt will be made to group the various remedies into categories to facilitate discussion.

Before considering the methods of treatment, it would be well to review the pathology of the average minor industrial burn. A frequent cause of the injury is brief contact with a hot object. For example, the following causes were listed in one weekly report from a plant: hot metal hot scale arc weld, cutting torch, steam blower, hot shaving. Another listed: burned finger on hot steel, burned chest on hot clamps, "burned forehead on lamp," "burned forearm on air hose." If we use the simple classification for the depth of burns, i. e. superficial or deep, most of these injuries would be classified as superficial burns, producing only a painful erythema. Others might be associated with vesicle formation, while the splash of molten metal may occasionally destroy the whole thickness of the skin.

What are we trying to accomplish in the treatment of these small injuries? Our aim should be to (1) prevent disability (get the man back on the job in a matter of minutes), (2) relieve pain, (3) prevent or minimize infection and (4) favor early healing, with a minimum of dressings. These objectives are different in many ways from those we have in mind when we are treating the serious burn in the hospital. In this instance we are concerned with saving the patient's life, which involves considerations of shock due to plasma loss, serious infection, scarring and contractures.

TANNIC ACID

Why has tannic acid been used in the treatment of minor burns? Probably largely because it has had wide acceptance in the treatment of serious burns, and theoretically what is good for a large wound should be good for a smaller one. The large burn is tanned in an attempt to prevent undue leakage of plasma and the resulting secondary shock. This is not a consideration in the minor burn. The large burn is treated with a coagulating agent to fix the injured proteins with the idea of preventing burn toxemia. There is no such hazard in the small burn. Furthermore, we now believe that under certain circumstances notably with slow drying of the eschar the tannic acid may have a specific toxic effect on the liver. Also tanning methods have not reduced the incidence of infection. The formation of an eschar requires that the part be left exposed to

the air for drying and that it be kept quiet for several hours. This would interfere with getting the man back on the job. One surgeon had this to say about the use of a brand of tannic acid jelly: "Our most serious complaint is that the dressing adheres to the medicated surface, making it impossible to remove the gauze without disturbing the crust formed by the ointment. Because of the necessity of keeping men on the job and the fact that the constant motion of the injured part tends to irritate the burned area, the usefulness of the dressing has not been demonstrated. A dressing of a lubricating quality seems to be adapted to industrial practice more readily than tannic acid jelly." There is considerable evidence that tannic acid delays epithelial regeneration.¹

In the recent study six brands of tannic acid jelly were reported. One brand was used in the treatment of 560 cases, with an average healing time of 7 days, each patient received an average of 5.6 treatments. Another brand of almost identical composition was used in 347 cases, with an average healing time of 3.7 days. It is not likely that there was actually a difference in

Report of Industrial Burns
Data requested for use by the National Research Council

Plant		Location		Plant Surgeon		
Report for week ending		Submitted by				
No.	Cause of Burn (Example)	Treatment	No. of Treatments	Days Before Healing	Days Lost	Days Hospitalized
1	Hot metal	Boric ointment	3	5	0	0
2	Steam	Tannic acid jelly	2	4	0	0

therapeutic response to these almost identical compounds, probably the discrepancy is due to differences in treatment practices and methods of keeping records.

GREASY OINTMENTS

In the study of greasy ointments it was reported that 182 cases were treated with boric acid ointment. The average number of treatments was 2.3 and the average healing time was 2.5 days. Plain petrolatum was used for 32 cases, with an average time of 2 days and an average of 1.7 treatments per patient. Seventy-three patients were treated with zinc oxide ointment. The average healing time was 6.4 days, the average number of treatments being 4.6.

When the tannic methods were in vogue it was considered unfortunate if a patient with burns arrived at the hospital with any sort of greasy ointment applied to his skin. Now there is a swing of the pendulum in the other direction, many groups who have had extensive experience in the treatment of burns use fine mesh gauze impregnated with petrolatum or 5 per cent boric acid ointment. There is disagreement on two points in connection with the treatment of burns in this manner: 1. How much should the wound be cleansed and debrided? 2. How much pressure should be used and

1 Taylor, Frederick. The Misuse of Tannic Acid, J. A. M. A. 106: 1144-1146 (April 4) 1936. Hirshfeld, J. W., Pilling, M. A., and Maun, M. L. A Comparison of the Effects of Tanning Agents and of Vaseline Gauze on Fresh Wounds of Man, Surg., Gynec. & Obst. 76: 556-561 (May) 1943. Cannon, Bradford, and Cope, Oliver. Rate of Epithelial Regeneration. A Clinical Method of Measurement and the Effect of Various Agents Recommended in the Treatment of Burns, Ann. Surg. 117: 85-92 (Jan.) 1943.

how important is it? One school, represented by Koch² of Chicago and Siler and Reid³ of Cincinnati, advise a very meticulous cleansing of the wound with white soap and water, using soft cotton instead of a brush. All shreds of epidermis are removed and all blisters are opened. Petrolatum gauze is then placed over the injured area, over this are laid a half dozen layers of flat dry sterile gauze, over this a mass of gauze fluff, and over the fluff mechanic's waste or sea sponges to provide even pressure when elastic bandage is applied.

There are a number of good surgeons who do not think that this meticulous cleansing of the burn is necessary. At the Coconut Grove fire in Boston, the patients admitted to the Massachusetts General Hospital had no "debridement" or cleansing, the burns were hastily covered with gauze impregnated with boric acid ointment and dressings applied over this. The results obtained in these cases were eminently satisfactory.⁴ It is well established that the unopened blister is not the infection hazard that it was once supposed to be. It may be that the best dressing for burned epithelium is the layer of plasma which has elevated the superficial layers of epidermis and formed a blister.

Therefore we are faced with the conclusion that the application of a petrolatum dressing following some type of cleansing is good treatment for burns both large and small. The next matter for consideration is whether or not there is an advantage in adding various chemical substances to the petrolatum. There is a long list of proprietary preparations composed of a petrolatum or similar base to which one to a dozen medicinal agents have been added. For example, one proprietary containing a shotgun collection of eleven drugs was used in the treatment of 1,285 burns. The average healing time was 6.3 days and the average number of treatments was 3.8. It was not superior to any of the emollient remedies.

VITAMIN OINTMENTS

The overemphasis of vitamin therapy in other fields has been extended to the treatment of burns. A number of commercial preparations have as active ingredients the fat soluble vitamins A and D. Cod liver oil appears to have been used first in Germany by Lohr and his associates.⁵ In 1939 they reported that they had treated 1,562 burns and scalds with cod liver oil and casts. There had been twenty-one deaths, or a mortality of 4.8 per cent. Only one of these deaths was due to late infection of the wound. The American literature contains a number of enthusiastic reports on the use of cod liver oil ointments in clinical cases.⁶ However, these clinical reports have that common fault: there were no controls. Brush and Lam⁷ found that commercial vitamins A and D ointment did not significantly affect the healing time of experimental cutaneous wounds in the guinea pig.

2 Allen, H. S., and Koch, S. L. The Treatment of Patients with Severe Burns, Surg., Gynec. & Obst. 74: 914-924 (May) 1942.
3 Siler, V. E., and Reid, M. R. Clinical and Experimental Studies with the Koch Method of Treatment of Heat Burns, Ann. Surg. 115: 1106-1117 (June) 1942.
4 Faxon, N. W., and Churchill, E. D. The Coconut Grove Disaster in Boston. A Preliminary Account, J. A. M. A. 120: 1383-1388 (Dec. 26) 1942.
5 Lohr, W., and Zacher, K. Zur Klinik und Pathologie von Verbrenungen 2 und 3 Grades Zentralbl. f. Chir. 66: 524 (Jan.) 1939.
6 Hardin, P. C. Cod Liver Oil Therapy of Wounds and Burns, South. Surgeon 10: 301-338 (May) 1941. Aldrich, R. H. Cod Liver Oil Ointment in Surgery, Indust. Med. 11: 153-157 (April) 1942.
7 Brush, B. E., and Lam, C. R. The Effect of the Topical Application of Several Substances on the Healing of Experimental Cutaneous Wounds, Surgery 12: 355-363 (Sept.) 1942.

In this statistical study of minor burns "cod liver oil" ointment was used in 25 cases, with an average healing time of 31 days. A commercial vitamins A and D ointment was used in 41 cases with an average healing time of 32 days. It should be remembered that the healing time of 32 cases treated with plain petrolatum was only 2 days.

FOILLE

Foille is a proprietary preparation described by the manufacturers as a stabilized water-in-oil emulsion accomplished through processing several drugs of well known therapeutic value in a vegetable oil base. Chemical action effects combination of certain elements and at the completion of the processing the active ingredients may be stated as follows: alcohol, benzocaine, oxyquinoline base, phenol, calcium soap, calcium iodide, potassium iodide and calcium thiosulfate.⁸ In this study Foille was used in 403 cases, with an average healing time of 5.9 days and an average of 5.3 treatments per case. This is no better (and probably no worse) than any of the other bland ointments.

SULFONAMIDE OINTMENTS

A number of ointments are available which contain one or more of the sulfonamide drugs. Those containing sulfathiazole and those containing sulfadiazine are more commonly used. A 20 per cent sulfathiazole ointment has been recommended by Dragstedt and his co-workers⁹ at the University of Chicago. A 5 per cent sulfadiazine ointment was used by Pickrell¹⁰ at the Johns Hopkins Hospital. Biram¹⁰ at the Colt's Patent Fire Arms Manufacturing Company treated 1503 burns by dusting with sulfathiazole and putting on "intracame" ointment. Only 2 patients lost time and there were no scars of consequence.

In this series the sulfonamide drugs combined in ointments were used in the treatment of 299 cases with an average healing time of 4.1 days. There is no evidence from this study or in other studies of major burns that the use of local sulfonamides is of value in the prevention of infection.

SUMMARY AND CONCLUSIONS

1. An unreasonable number of different preparations are being used for the treatment of minor burns in industrial plants.

2. Regardless of what is put on the average minor industrial burn, it is apt to be healed in less than a week.

3. We recommend the following treatment for minor industrial burns:

- (a) Wash the area with white soap and water.
- (b) Do not break blisters or otherwise "debride" the wound.
- (c) Cover with fine mesh gauze impregnated with petrolatum or 5 per cent boric acid ointment.
- (d) Apply a firm dressing over this, bulky enough to keep dirt away from the injury but not too large to keep the man off his job.

NUTRITIONAL REHABILITATION OF ONE HUNDRED SELECTED WORKERS FOR INDUSTRY

TOM D. SPIES, M.D.

BIRMINGHAM, ALA.

The present study might well be said to have begun in 1930, when I realized that persons with deficiency diseases were unbelievably weak and listless. The first six years were spent in the careful study of 278 patients in Ohio, selected because they had lesions typical of pellagra, beriberi or scurvy.¹ In 146 of these patients the nutritional deficiencies were secondary to organic diseases which interfered with the proper ingestion, absorption or utilization of a good diet, in 115 patients they followed chronic alcoholic addiction which interfered with the ingestion of an adequate diet, in the other 17 patients they were of the endemic type which follows the habitual consumption of a diet poor in essential nutrients. All the 278 patients were severely ill and were admitted to the hospital for careful clinical study. Invaluable aid in carrying out these studies was given from time to time by Drs. A. B. Chinn, Warren Payne, A. S. Dowling, H. F. deWolf, John Ambler and W. Clark Cooper. In these studies our efforts were directed particularly toward determining in each patient the predisposing and precipitating factors concerned in the development of the disease and the individual response to treatment. After the patients were discharged from the hospital, our frequent visits to their homes and their visits to the clinic revealed that in each instance the gain in strength had been spectacular. Many of them had returned to work and were extremely grateful for having better health. The 17 patients in the endemic group offered a special challenge in that they were able to obtain work and wanted to know ways of remaining in good health so that they could continue this work. The response of these 17 patients to treatment suggested to us that we seek an agricultural and industrial area in which deficiency diseases were endemic. Accordingly, when we were given an opportunity to go to such an area in Alabama in 1936 we accepted. It seemed to us that the first thing to be settled was whether or not the pellagra we had been treating in the North was the same disease that was so common in the South. This we did by applying the methods of treatment we had used in our cases in Ohio to 50 cases of endemic pellagra in and around Birmingham, Ala.² Our results were as successful as those we had obtained in Ohio, thus indicating that the response to therapy in endemic nutritional deficiencies was the same in the North as in the South. Our next problem was to test our original hypothesis which was that persons debilitated by nutritional deficiencies can be rehabilitated so that they can return to work, provide a good diet for themselves and family, and thus rehabilitate not only themselves but perhaps other members of the family.

University of Cincinnati Studies in Nutrition at the Hillman Hospital, Birmingham, Ala. From the Department of Internal Medicine, University of Cincinnati.

The tremendously heavy expenses of the general nutrition study have been borne by grants from a number of philanthropic persons, foundations and commercial concerns without which this study could not have been done. The necessary expense of frequent observations of these patients in their homes and in the clinic over a long period of time has been defrayed by grants from the John and Mary R. Markle Foundation and Parac Davis and Company.

² Spies, Tom D., Chinn, Austin B. and McLeer, James B. Severe Endemic Pellagra. *J. A. M. A.* 108: 823 (March 13) 1937.

My purpose in this communication is to call attention to the fact that persons debilitated solely by nutritional deficiencies gain strength promptly following specific nutritive therapy. Certainly it should not be inferred that nutritive therapy is a panacea for all weak, listless but willing workers. I realize that persons who do not have nutritional deficiencies will not be benefited by such treatment. As will be seen, however, the very nature of the present study was such that I could rigidly select patients who could be fitted for work in industry because they were debilitated solely by nutritional deficiencies. In every instance their health was restored and they were able to return to work. The study is being continued but, because of the present great need for manpower, I deemed the results thus far worthy of publication.

MATERIAL AND METHODS

Indigent persons were referred to the Nutrition Clinic from the emergency ward and the outpatient department of the Hillman Hospital, from private doctors in Birmingham and nearby communities, or by other patients. In the latter group were a number of persons who had symptoms which they considered similar to those of patients already under our care. To us it was interesting that, in a local community in which our treatment of a person with some particular symptom had been followed by spectacular improvement, other persons in the community with similar symptoms flocked to us, for example, following the relief of pellagrous psychosis in a patient, many persons with mental symptoms were brought to us from miles around. We then had to decide whether or not the mental symptoms of these persons could be explained on the basis of nutritional deficiencies and, if they could not, we had to make arrangements for them to be treated elsewhere. Similarly, when the treatment of persons with ulceration of the cornea due to riboflavin deficiency was followed by great improvement, persons with various ocular symptoms heard about it and came seeking relief.

In the first month we thought in terms of the individual rather than of the family, with the result that we probably missed a certain number of patients in the various families. We soon learned, however, that when we made a diagnosis of nutritive failure in one person it was desirable to study the family as a group. This proved to be logical in view of the fact that they all ate from the same table. From the afflicted family we selected a potential worker between the ages of 15 and 60 and applied the criteria for the present investigation. From several thousand persons with deficiency diseases we made a very rigid selection of cases for this study.

In initiating the rehabilitation of these patients, we obtained all the available information about the person as well as his disease. In assembling such information, no mere outline sufficed in all details for every patient. Nevertheless, certain forms which we used were helpful. These forms, along with the ones used for the mixed symptom complex, are described in a recent publication.³

By long experience we learned that the very essence of successful therapy is early and accurate diagnosis and that the diagnosis can best be made by a conservative interpretation of all the data secured from

a dietary survey, special laboratory determinations, a complete medical history and a physical examination. When we first saw a person with the idea of selecting him for this study, we obtained a dietary history from the potential patient as well as from others in the family. We questioned them carefully in regard to the amount of each food they ate daily. We made frequent visits to their homes to collect data on their actual food consumption. By comparing the foods these persons ate with those recommended for an adequate diet, we estimated approximately the adequacy of their diets. It was found that information in regard to the family income and their food resources, such as a garden, chickens and cows, was of great value in determining the adequacy of the food intake. If the income was very low and there were few or no food resources, it seemed likely that their diets had been inadequate.

From the beginning we realized that deficiency diseases tend to occur as complexes rather than as single entities. Many of the patients included in this study had presenting evidence characteristic of more than one deficiency disease. Nearly every patient gave a history of having had symptoms which, for a number of years, waxed and waned with the seasons and in most instances became worse each year. The attack which brought them to the hospital at this time was more severe than that of previous years. Many of them said that they had not gone to a physician because they realized that they had pellagra and felt that it was a disgrace. When their vague early symptoms began, some of them had gone to a physician, who in many instances made a diagnosis of hysteria, neurasthenia, anxiety states, functional disorders or just plain neurosis.⁴

In the final analysis a definite diagnosis of nicotinic acid deficiency (pellagra) was made only when the patient had pellagrous mucous membrane lesions or pellagrous dermatitis, the diagnosis of thiamine deficiency was made only when the patient had characteristic nutritional neuritis, we diagnosed scurvy only in the presence of scorbutic gums and hemorrhages into the skin or tissues. For the first three years we selected only persons who had characteristic pellagra, beriberi or scurvy. More recently we have included also persons with diagnostic evidence of riboflavin deficiency. The signs on which we depended for a diagnosis of riboflavin deficiency were cheilosis at the angles of the mouth or characteristic ocular lesions. It is of interest that, in 100 patients arbitrarily selected for this study, niacin deficiency was diagnosed in 56, riboflavin deficiency in 50 and nutritional peripheral neuritis in 24. These figures total more than 100 per cent because two or three types of deficiency were present in 25 patients. Associated with these diagnostic lesions in 100 selected patients we could list pages of other symptoms, but in every instance we found weakness, failure of mental application, nervousness and irritability. In each case we determined whether the nutritional failure was due to an inadequate diet, alcoholic addiction or organic disease which interfered with proper nutrition. After making a positive diagnosis of nutritional deficiency in a potential worker who was unable to work, we discarded for this study any one whose history even suggested predisposing factors other than an inadequate diet. When it was secondary to a chronic disease or alcoholic addiction, the patient was treated but was not included in this particular investigation.

3 Spies, Tom D., Bradley, John, Rosenbaum, Milton, and Knott, John R. Emotional Disturbances in Persons with Pellagra, Beriberi and Associated Deficiency States, Res. Pub. Assn. Nerv. & Ment. Dis. 22: 122, 1943.

4 Spies, Tom D. Diagnosis and Principles of Treatment of Deficiency Diseases, Texas State J. Med. 38: 427 (Nov.) 1942.

From the beginning, the criteria for the selection of patients, white or black, was the same. We were impressed by the small number of Negro patients who came to us. Particularly were we impressed in view of the fact that the population of the locality in which we were working is about 50 per cent white and 50 per cent colored. Of the 100 patients selected, only 1 was a Negro.

While I have seen every patient in the clinic as well as those described here a number of times, it would have been impossible for me to care for the large number of patients treated in the clinic or hospital or to have carried out all the details of this study had it not been for the willing, intelligent cooperation of the following associates at various times through the six years: Drs. Robert E. Stone, Richard W. Vilter, William B. Bean, Luther Terry, Irvin H. Griffin, L. H. Hubbard, D. P. Hightower, Frederick A. Dowdy, T. S. Boozer, Brad Morris, Sam Jones, H. H. Henderson, Sidney T. Wright, Esther S. Gross, A. S. Turk, Gilbert F. Douglas, Jr., Norris L. Brookens, Walter B. Frommeyer, Jr., Daniel Perry and Robert C. Cogswell, Jr. These doctors and Misses Ann Van Blaricom and Monette Springer and Mrs. Jane M. Mann, nurses, and Misses Helen M. Grant and Jean M. Grant, Mrs. Merle S. Babb and Mrs. Mabel Morey, nutritionists have for the most part spent their time on the hundreds of patients who have been treated and returned to work on the farm or have improved so that they could do their housework or have been accepted by the armed forces. The following consultants have seen certain of these patients and have given freely of their knowledge, time and diagnostic acumen, and to them also I am grateful: Dr. Charles D. Aring, J. P. Frostig, F. H. Lewy, H. E. Himwich, Milton Rosenbaum, John Bradley, John R. Knott, Emory D. Warner, Carl V. Moore and A. W. Mann.

TREATMENT

After selecting the patients we immediately initiated therapy and then began the long, arduous task of eliminating all the factors which predisposed to or precipitated the nutritive breakdown.

In the beginning it was necessary to admit most of the patients to the hospital for intensive as well as persistent feeding and therapy. More recently they have been treated in the clinic and allowed to return home. Of late we have been especially gratified to see the period of convalescence greatly shortened by the application of the newer methods of treatment.

The dietary treatment of these selected persons with deficiency diseases, whether they were treated in the hospital or in the clinic, was based on the principles of nutrition applicable to persons in health. We realized that it was essential for these patients to have an adequate intake of protein, calories, water, minerals and vitamins. We realized also that in persons with deficiency diseases the nutrition of the body has suffered considerably. Accordingly the diet, although based on the principles of the normal diet, was planned so as to supply much larger than normal amounts of the essential nutrients. Each patient was given a diet which supplied at least 4,000 calories, 120 to 150 Gm. of protein and liberal amounts of minerals and vitamins. In the beginning, the type of food used and the method of administering it depended entirely on the ability of the patient to ingest and retain food. As a rule the desire for food was absent. At first it often was necessary to give small feedings at frequent intervals. In the severe cases the mouth and tongue were often

so sensitive that only liquid or soft foods could be given and highly seasoned or acid foods had to be avoided. As these patients improved, semisolid and solid foods were given and a greater variety of food included in the diet. In all cases in which diarrhea was present solid foods were added as soon as possible. Whether the diet was liquid, soft or solid, every effort was made to prepare and serve it in such a way that it was most acceptable and attractive to the patient.

We never relied on food alone to relieve the vitamin deficiencies. Supplements of the nutrients in which the patient was deficient were always given. Until synthetic vitamins became available for clinical use, we depended entirely on such substances as brewers' yeast powder, liver concentrates and citrus fruit juices as supplements to the diet in the treatment of deficiencies of the water soluble vitamins. As valuable as these substances were and still are, there are times when synthetic substances are life saving.

Since vitamin deficiencies usually are multiple rather than single and since, in our experience, we have found that severe deficiencies of the water soluble vitamins are much more common than those of the fat soluble group (A and D), of late we have used a basic formula composed of a mixture of the water soluble vitamins in treating the clinical syndromes of beriberi, pellagra, riboflavin deficiency and scurvy. This formula contains 10 mg. of thiamine, 50 mg. of niacin amide, 5 mg. of riboflavin and 75 mg. of ascorbic acid. When the symptoms of one deficiency predominate, more of the vitamin specific for the predominating deficiency is added. In the case of beriberi, 10 mg. of thiamine was added daily; in riboflavin deficiency, 5 mg. of riboflavin was added twice daily; in scurvy we added 100 mg. of ascorbic acid three times a day. To the severely affected pellagrin, 150 mg. of niacin amide three times a day was given in addition to the basic formula. Two patients were so severely ill that we chose to administer these substances parenterally.

When convalescence was established in patients with B complex deficiencies who had been treated with synthetic substances, dried brewers' yeast powder or oral liver extract was given as a supplement to the diet. These substances contain significant amounts of protein and other nutrients and they are particularly valuable because they supply essential substances in which the patient is probably deficient as well as the B complex vitamins. The amounts of these substances that we gave depended on the severity of the disease. Usually we gave daily doses of from 4 to 6 ounces of dried brewers' yeast powder or oral liver extract.

OBSERVATIONS

As can be seen from the 2 representative cases the response to immediate therapy in all cases was rapid. These cases like the others were selected at a time when jobs were scarce and the competition for them was great, even among skilled competent workers. Many of the persons selected volunteered the information that they could not compete with better nourished and more physically fit workmen.

The following case history is that of a young boy whose father worked in a steel mill, had a good income, owned his own home and provided an adequate diet for the family. As a result of idiosyncrasies in diet this boy became an invalid. Following treatment, he was able to complete his education, obtain a job and become self supporting.

CASE 1—History—R. M., a 15 year old white boy, unable to walk or stand alone, was carried into the clinic of the Hillman Hospital, March 12, 1936. The family history was negative. The past history was irrelevant. From the parents and later from the boy it was learned that he was in perfect health until January 1935. At that time he began to lose his desire for food and soon began to lose weight. Since his appetite was so finicky, his mother stated that she allowed him to eat anything he wished, so he restricted his diet to desserts, candy and soft drinks. Early in March his mother noticed discoloration and roughness over his elbows and knees. These lesions persisted, he continued to lose weight and by September was so weak he could not go to school. In October he became acutely ill and was admitted to a hospital for observation. The redness of his tongue led some physicians to suggest that he might have scarlet fever. Others suggested that he might have nephritis because of the edema of his ankles. At this time he had some pain and numbness in all four extremities. After a ten day period of observation in the hospital he was discharged. A month later he began crying a great deal of the time because of the intense, persistent pains in his legs and arms. His feet burned so much that he refused to have bedclothes over them. By this time he was listless, lost interest in everything and refused to see any of his friends. Gradually he became apprehensive and dull and was no longer able to use his legs and arms. By the end of the year he could not walk or stand alone and was unable to hold a glass or feed himself. Early in February a physician told his parents that the boy had multiple sclerosis. A month later his tongue and mouth became sore again and a "rash" appeared on the elbows and legs, and new areas were involved on the forearms, nose and cheeks. The physician now said that the boy had pellagra and suggested that they take him to the Nutrition Clinic.

Nutrition History—The boy was breast fed until he was 18 months of age, he was not given supplements of cod liver oil or orange juice. From the time he was old enough to eat solid food he preferred bread, desserts and sweets to any other foods. Prior to his illness he often ate 10 to 12 slices of white bread, 4 or 5 servings of desserts and large amounts of candy daily. Usually he drank from 5 to 6 bottles of some kind of soft drink daily. Occasionally he ate small servings of greens or tomatoes and sometimes an apple but would eat no other fruit or vegetables. He refused all meats except lean pork, which he ate once or twice in a week. He had not had milk or eggs since he was 2 or 3 years of age. As the father had regular work in the steel mill, owned his home and supplied adequate food for the children, it is fair to say that the boy's food idiosyncrasies were the reason for his not having an adequate diet. Nutrition histories of two sisters, a younger brother and the parents showed that they had always eaten adequate diets.

Physical Examination—The boy was listless, depressed, undernourished, apprehensive and uncooperative. The tongue and buccal mucous membranes were cardinal red and swollen. Large, symmetrical "butterfly" dermal lesions of pellagra extended over the bridge of the nose and the malar surfaces of both cheeks. These areas were pruritic and dark brown with a fiery red border. The line of demarcation between the pellagrous areas and the surrounding skin was clearcut. The skin over the dorsal surfaces of the elbows and knees looked and felt like rough sand paper. It was thickened, inelastic and bronze in color except at the edges, where it was fiery red.

Neurologic Examination—The boy was unable to walk or to move any extremity. The muscles of the hands, forearms, thighs and legs showed profound atrophy. The hands were "clawlike" in appearance, the deformity was somewhat greater in the left than in the right. The muscles of the legs and arms were weak and there was almost complete loss of power of the dorsiflexion of the lower arms, resulting in bilateral wrist drop. There was extensive atrophy of the muscles of the thighs and lower legs. He had bilateral foot drop. The biceps, triceps, patella and achilles reflexes were absent bilaterally. Babinski, Gordon and Oppenheim signs were not present, and there was no ankle clonus. The abdominal and cremasteric reflexes were present and active. There was no evident disease of any cranial nerve.

Course in the Hospital—He was put on twenty-four hour nursing service and was under the supervision of a dietitian and a number of physicians in addition to the house and visiting staff. He was given a daily diet of 4,000 calories, rich in meat, milk and eggs, supplemented with 180 Gm of dried brewers' yeast powder. The yeast was given in 30 gram amounts, well mixed in 200 cc of ice cold milk. The first two days he could retain the food and yeast mixture only when they were given in very small amounts at frequent intervals, so he was fed at least every two hours day and night. By the third hospital day he had improved and his food was given in more solid form at less frequent intervals and the yeast mixture was given every four hours. His diet included daily 1 quart of milk, 4 eggs, $\frac{1}{2}$ pound of lean meat, 2 servings of green vegetables and 2 servings of fruit, in addition to liberal amounts of whole grain cereal, bread, butter and cream. Although he refused to eat these foods at home and had not tasted many of them before, we insisted that he eat them. He never learned to like carrots or beets but developed a liking for all other foods. After his general sense of well-being began to improve, the redness of the buccal mucous membranes and the tongue faded rapidly and he stated that his mouth and tongue no longer burned. The erythematous borders of the skin lesions faded promptly, began desquamating and within one week had subsided except for a residual pigmentation.

For the first two days in the hospital he was so apprehensive, frightened and antagonistic that little could be done with him other than force food. On the third hospital day he began to chat with other patients and became very friendly with the doctors and nurses during the subsequent week. By this time he was able to move his legs in bed and began to use his hands to help feed himself. Soon afterward he was allowed in a wheel chair and was able to push himself around and started playing checkers with other patients. When he was discharged on his twelfth hospital day he seemed well on the road to recovery and had gained 6 pounds (27 Kg). His mother promised faithfully to follow instructions in regard to preparing and serving his diet, and the boy agreed to eat what ever she gave him. This system worked well. Two weeks after he left the hospital he was able to stand alone and soon began walking on crutches. Two weeks later he was able to walk around the house without crutches and within six weeks was riding a bicycle. By September he had gained 18 pounds (82 Kg) and decided to return to school. In 1940 he graduated from high school and went to work driving a truck for a chain grocery. In December 1942 he was given a much more responsible job with the same company driving a large transport truck over long distances. At present he works steadily, has an excellent appetite and eats the kind of food he was instructed to eat. Like the proverbial fairy story, he is married and living happily and expects soon to become a member of the armed forces.

The following representative case is that of a highly skilled workman who was on the verge of being sent to a custodial home for mental diseases as a result of nutritive failure. His illness appeared soon after the plant in which he worked closed. He subsequently stated that without special treatment he could not have improved sufficiently to secure and hold a job. He said he noticed that better nourished and more physically fit men were the first to be selected to return to work when the steel plants reopened.

CASE 2—History—K. J., a 33 year old white foundry worker in a steel mill, was brought to the Hillman Hospital by his wife on March 16, 1936. The past history was negative. The patient had been in good health until January 1936. When he was finishing his last year in high school his father who had always had a good income, died suddenly, and in order to support his mother and two brothers the patient obtained work in a steel mill. We learned from the superintendent of the mill that he was a skilled, reliable worker, that he was exceptionally conscientious and that he soon learned to be one of the best molders in the foundry. He was made foreman of the shop in 1926, when he was only 23 years of age. At this

time he married and began making payments on a small house and $\frac{1}{2}$ acre of land. Within three years three children were born, and in order to provide them with the best food possible he bought a cow and chickens and grew vegetables and fruit, much of which his wife canned for winter use. At this time the family lived comfortably and had a liberal and well balanced diet. Late in 1929 the mill began operating part time, but for more than a year he made enough money to avoid drawing on his insurance and he continued to make small payments on his house. By 1931 the mill had closed and he was out of a job. His savings dwindled until they disappeared. He sold the cow and chickens which he could no longer buy food for them. Next he sold most of the house furnishings and divided the money with his two brothers who were also unemployed. Occasionally he obtained work in a lumber yard but earned only enough to provide a little milk for the children, scant fuel for the kitchen stove and some seeds for the garden. He worried much of the time about his wife and children and decided that in order to give them the best of what food there was he would tell them he preferred to eat grits, corn bread and syrup. He followed this self imposed diet and gradually lost all desire for food. For many days he ate biscuits and drank coffee in an attempt to get enough energy to work in the garden. In January 1936 his wife observed that he was doing very peculiar things such as getting up at night and pacing the floor or walking around the garden, hours at a time talking or mumbling to himself. He was confused and in the middle of a sentence frequently forgot what he had started to say. When he went on an errand he often forgot where he had started and for what purpose. Despite the fact that he had always been devoted to his family he became so irritable that the children were afraid of him and his wife hid them from him. Although he could not tolerate having the children near him he refused to allow them to go to school because they did not have what he considered the proper clothing. For the first time in his life he developed such a belligerent attitude toward his neighbors and friends that they stopped visiting him. Later he refused to go out of his house for weeks at a time. Early in February he began complaining of pain and burning in his stomach and burning and aching of his feet. The burning was so intense that he could not sleep and he sat up most of the night with his feet in a tub of water. He refused to have bedclothes over them although the house at this time was very cold. A little later he began to complain of a sore mouth and tongue, and by this time the pain in his stomach was so severe that he refused to eat anything but thin gruel made from grits and to drink an occasional cup of coffee. Soon after that his wife noticed that the skin on his hands, forearms and neck became fiery red. He thought he had something catching and issued orders that his wife and children must not enter his room. He lay in bed shouting to his wife that he had made a failure of his life and brought disgrace on his family and he threatened to kill himself and them. He refused her offer to have a doctor on the basis that the doctor would poison him and probably would steal the children and give them to the neighbors. His wife became so alarmed by his actions that she went to his former employer and asked his assistance in having him committed to a custodial institution for the treatment of mental diseases. The employer called a physician who from the skin lesions made a diagnosis of pellagra and prescribed a sedative and the patient was brought in an ambulance to the Nutrition Clinic of the Hillman Hospital. From there he was admitted to the ward.

Physical Examination—The patient was well developed but emaciated and appeared irritable and depressed. Large symmetrically placed erythematous pellagrous lesions extended over the dorsum of the hands, the wrists and the forearms and completely encircled the neck. The tongue and mucous membranes were swollen and reddened. The knee jerks were greatly hyperactive. The peripheral nerves of the legs were excruciatingly tender to pressure.

Treatment and Course—He was placed under twenty-four hour nursing dietetic and medical supervision. He was given daily a diet of 4000 calories, rich in meat, milk and eggs and 120 Gm. of dried brewers' yeast powder. Although he usually

objected to taking food, complaining that it "scalded his tongue, burned his stomach and made his bowels move too often," by coaxing he was persuaded to eat the desired amount, even on the first hospital day. Since he could eat only a little food at one time, we fed him every hour day and night. He seemed rational at intervals during the first two days but most of the time he was having hallucinations and delusions, frequently manifested by his persistent insistence that his wife was waiting downstairs in the hospital for him to sign a pay check, despite the fact that his wife was at home and that he had not received a pay check for a long period of time. Occasionally he thought we were trying to poison him but this idea was fleeting a few minutes after refusing food he might take the same food without hesitancy. By the third hospital day the redness of the tongue and the oral mucous membranes had disappeared. He said that he felt fine, asked for food and volunteered that he had been "out of his head" for a long time. By this time the skin lesions were fading and by the tenth hospital day they had desquamated. The burning and aching of his feet steadily lessened, and he was discharged ten days after admission, having gained 10 pounds (4.5 Kg.) in weight. He now had an excellent appetite, was cheerful and anxious to return home to his family and felt confident of obtaining employment. He followed the recommended diet at home and visited us in the clinic twice during the next week. The superintendent of the foundry gave him work three days a week. The patient asked our counsel as to how to provide an adequate diet for himself and his family on his new income. He followed our suggestions and remained well until February 1938 when he developed a protracted illness diagnosed by the attending physician as influenza followed by bilateral lobar pneumonia. After a stormy convalescence he gradually recovered but was very weak. During his illness he lost his appetite and 20 pounds (9 Kg.) in weight. Three weeks after the pneumonia subsided he noticed burning of the mouth and tongue and burning and aching of the feet soon became so severe that he could not sleep. He worried constantly about his family. His wife was sure he was going out of his head again. He became uncooperative and was reluctant to see us or his friends. He was so depressed that he no longer cared for our counsel. His wife came to see us and we advised her to bring him to the hospital. He did not want to come and she did not wish to urge it at this time. Two weeks later the skin on his hands, forearms and neck became fiery red. In a lucid moment he realized that his symptoms were similar to those we had treated before, so he asked his wife to get a car to bring him again to the Nutrition Clinic.

Between these two attacks of deficiency disease the science of nutrition made rapid progress. The patient remained ambulatory, coming to the Nutrition Clinic for treatment daily for the first three days, then twice a week for four weeks. For three days he was given 500 mg. of nicotinic acid daily in ten 50 mg. doses, then four 50 mg. doses daily for four weeks. His wife gave him 120 Gm. of dried brewers' yeast powder each day in tomato juice. The day after treatment was started he volunteered that he felt better again that his head was clear and that his mouth and tongue no longer burned. The redness of the tongue and buccal mucous membranes faded within twenty-four hours. By the third day the redness of the skin lesions had decreased and on the fifth day were well on the way to desquamation and healing. At the end of two weeks he still complained of some aching of the legs and burning of the feet and as a therapeutic test he was given an injection of saline solution which did not relieve this pain. The next day he was given 10 mg. of thiamine intravenously and within thirty minutes had complete relief from pain. That night he slept better than he had slept for years. He was then given 10 mg. of thiamine twice daily by mouth for four weeks. Within two weeks the burning of his feet had disappeared. Once again he was instructed to eat a liberal diet but this time he objected because of the cost. He thought he would not be able to go back to work for some time and feared that if he ate the recommended diet there would be no food for his family. He consented to follow instructions only when we told him he probably would be able to go back to work in a week if he followed directions. His former employer gave him several days work each week and within three months he was working

six days a week as foreman of the foundry. He continued in this job until the summer of 1941, when he was offered a responsible position in the Navy Yards on the east coast. Since this paid more than the job he had, he decided to try it for a few months. After staying two months he found he enjoyed the work and came back, sold his house and moved his family. Although we made frequent examinations of the wife and children, we never found diagnostic lesions. Nevertheless they were underweight, nervous, irritable and apprehensive. As the patient's health improved and he obtained employment, he was able to provide a better diet for himself, his wife and his children. The general health of his wife and children as well as his own improved steadily. In his last letter he stated that he had not lost a day's work in over a year and that his family were in excellent health.

These 2 patients, like most of the others in the study, have made frequent visits to the Nutrition Clinic, and we have made visits to their homes from time to time, with the result that we were able to keep them under supervision. Many of the patients still take daily supplements of yeast, yeast concentrates or synthetic vitamins. All the patients except 1 white man improved to the place where they wished to get jobs and proceeded on their own initiative to do so. The 1 white man who improved but was not interested in obtaining a job volunteered and was accepted in the Army Engineer

Distribution in Industry of One Hundred Rehabilitated Workers

Miners	25	Cotton mill workers	2
Steel mill workers	14	Painters	2
Saw mill workers	8	Casket factory workers	2

Corps. Some idea of the type of jobs they obtained in the various industries can be seen from the accompanying table.

SUMMARY AND CONCLUSIONS

1. One hundred persons, debilitated solely by nutritional deficiencies to the point where they could not work, were selected and treated. In every instance the immediate response was gratifying. Persistent therapy enabled these persons to obtain work and to continue to work and earn sufficient funds to provide an adequate diet. Being grateful and anxious to cooperate, they have followed our dietary instructions with the result that there has been a slow but steady improvement in their health and, in many instances, in the health of their families.
2. The disease in case 1, which followed an idiosyncrasy in diet, is considered representative of deficiency diseases which occur among both rich and poor, anywhere, at any time. Case 2 illustrates how easily symptoms arising from faulty nutrition of the nervous system can be confused with neurotic and psychopathic states of undetermined origin.
3. The science of nutrition has advanced so rapidly that the practicing physician naturally wonders what can be counted on in his day to day practice of medicine. Certainly he will be gratified if he makes an accurate diagnosis and applies persistent therapy to a debilitated, potential worker who is held back solely because of inadequate nutrition.

Hillman Hospital

THE PRESENT STATE OF THE ARMY'S HEALTH

BRIG GEN JAMES STEVENS SIMMONS
Director of the Preventive Medicine Division, Office of the Surgeon General, U S Army
MEDICAL CORPS, ARMY OF THE UNITED STATES

The United States Army is now faced with the largest and most complex problem of health protection that has ever confronted a military force. Aside from the few zones controlled by the enemy, our forces circle the globe. They are exposed to wide variations of weather and climate, they live under conditions ranging from the best that modern civilization can offer to the worst that exists among aboriginal savage tribes, they must be protected, not only from the diseases of our own country, but from the serious infections that have played a dominant role in retarding the progress of civilization in certain foreign lands. It is no exaggeration to say that the Army is now, or soon will be, confronted with almost every known disease.

The protection of the health of our military forces under such adverse conditions is a matter of great concern not only to the Medical Department of the Army but to the entire medical profession of this country.

In the present article I propose to take stock of the results of the Army's program of preventive medicine as indicated by the present state of the Army's health. The present excellent health record can be best appreciated when contrasted with the Army's past experience with disease.

During the century and a half of our national existence the United States Army has had a rich experience with disease in peace and in war, at home and abroad. The peacetime experience has to a large extent paralleled that of the civilian population, and the health of the peacetime army has improved along with that of the country as a whole. However, mobilization and war always introduce conditions that favor the spread of disease and render difficult the efficient application of the measures available for their control. Therefore it is important to compare our present health record with the records of previous wars.

Beginning with the American Revolution there has been a progressive improvement in the care afforded the sick and wounded. However, in each of our wars the infectious diseases have produced more disability and death than have the injuries of battle. The nature and severity of these infections have differed greatly, depending on circumstances, but prior to the twentieth century the most disabling of the wartime diseases were included in the enteric, respiratory and insect borne groups. In the Mexican War disease caused seven times as many deaths as did battle. During General Scott's campaign dysentery, typhoid, cholera, malaria and yellow fever caused losses exceeding 30 per cent of the effective strength of his forces. In the Civil War about six million Union soldiers were admitted to hospital for disease and the reported deaths were as follows: battle injuries 94,000, disease 186,000, and unknown 24,000.

During the Spanish-American War information was available about many of the micro-organisms of disease, but military hygiene and sanitation were still unde-

Second lecture in the sixth series of lectures under the John W. ...
Lectureship, established by the Phi Delta Epsilon Fraternity, New York
University College of Medicine, April 16, 1943

veloped. Consequently we again lost seven men from disease to every one killed in battle. One fifth of all the troops developed typhoid, which caused 80 per cent of the total deaths. Malaria and other diseases were also prevalent.

When our Army entered World War I, two decades later, it was better prepared to meet the challenge of certain of the infectious diseases. Great advances had been made in bacteriology and protozoology, and military preventive medicine had become a highly developed science. Between April 1917 and December 1919, four million men were mobilized. All of these troops were vaccinated against smallpox, typhoid and paratyphoid A and B. Methods were available for the sterilization of water in the field. There were 50,000 battle deaths and only 58,000 attributable to disease. Typhoid was uncommon, but the respiratory infections were prevalent and influenza appeared in virulent pandemic form. As our forces operated mainly in temperate regions, the so-called tropical diseases were comparatively unimportant.

During the next two decades of peace the Army's health record was excellent. As shown in chart 1, the admission rates per thousand per annum reached an all time low in 1939 of 529 per thousand. As shown in chart 2, the decrease in mortality has been even more dramatic and in 1939 the rate reached 3.1 per thousand, the lowest mortality rate experienced up to that time by the United States Army.

With this wonderful health record we entered the period of emergency that preceded the present war. At that time it was impossible to predict what diseases might arise to attack our forces. Past experience indicated clearly that this would depend on many complex factors including geographic location, climate, season, local health conditions in the areas involved and the protection afforded our troops. Therefore all of the wartime plagues were considered as potential hazards and comprehensive plans were made to combat them. These plans resulted in an extensive program of preventive medicine. This program has been developed

Chart 1—Annual admission rates per thousand strength U S Army since 1900

by the Preventive Medicine Division of the Office of the Surgeon General of the Army through its various branches, including Sanitation, Sanitary Engineering, Laboratories, Occupational Hygiene, Epidemiology, Venereal Disease Control and Medical Intelligence. The results of the program to date will be discussed under the general categories of wound infections, nutritional diseases, gastrointestinal diseases, respiratory diseases, insect borne diseases and venereal diseases.

WOUND INFECTIONS

In no field of military medicine has the effect of modern surgical and prophylactic methods made itself felt with greater force than in the management and treatment of battle casualties. The wounded soldier in this war has a much greater chance of surviving than did his predecessor in World War I. Prompt evacua-

Chart 2—Deaths, all causes excluding battle injuries annual rates per thousand strength U S Army since 1900

tion of the wounded from the battle line, improved methods of transportation and the moving forward of aid stations and surgical units whenever possible make for earlier treatment during the "golden six hours" following injury.

The use of blood plasma to combat shock and of the sulfonamides to control wound infections has resulted in the saving of thousands of lives. During 1941 the Army adopted immunization with tetanus toxoid as a routine procedure for all personnel. So far we have had no tetanus among those immunized.

The problem of gas gangrene is still unsolved, although prompt use of antitoxin, the sulfonamides and improved surgical treatment have led to a pronounced decrease in deaths from this infection. There is great need for an effective prophylactic agent for use against the gas gangrene anaerobes. An intensive search for such an antigen has been under way for several years, and it is hoped that eventually we may have an effective prophylactic for use against these serious complications of battle wounds.

NUTRITIONAL DISEASES

No discussion of military preventive medicine would be complete without some consideration of the nutritional deficiency states. This subject is of growing importance since the production and distribution of food has been seriously dislocated in many parts of the world, and in certain parts of occupied Europe the population is actually faced with starvation. It seems reasonable to predict that the food situation in all countries will grow worse before it grows better.

The United States Army is the best fed force in the world and there is no reason to believe that it will not remain so. However, this applies only under stabilized conditions and when there is no interruption of the flow of supplies. There will be times however, when troops are cut off from their supply bases and must subsist on emergency rations or lacking these on what food they can glean from the countryside.

During the last three years the Army ration has been a subject of intensive study. In 1940 an expert on nutrition was placed on the staff of the Surgeon General, and well trained nutrition officers are now assigned to

duty with every large command in order to maintain a close check on the quantity and quality of the soldier's food

Various types of field rations have been developed for different special uses. Field ration A is the ordinary ration used in the training camps and elsewhere when possible. It contains a maximum of fresh foods. Field

Chart 3—Typhoid and paratyphoid annual rates per thousand strength white enlisted men in U. S. Army since 1900. Typhoid vaccination was voluntary in 1909, was compulsory a portion of 1910 and has been compulsory since 1911. (U. S. Army Medical Museum file No. 70877)

ration B consists of foods that do not require refrigeration, such as canned fruits and vegetables, canned or preserved meats, potatoes, onions, flour and so forth. This ration is supplied for troops on maneuvers and to expeditionary forces. It should be supplemented by local supplies of fresh foods when available. For convenience the B ration is packed in cartons containing sufficient food for the daily use of either 5 or 10 individuals.

Field ration C is concentrated and requires no cooking. It has been devised for use in places where the transportation and preparation of food are difficult. It consists of three cans containing hash, meat and beans and meat stew respectively, also three cans each containing biscuits, a beverage, sugar and candy.

For special occasions where light weight and lack of bulk are necessary, a pocket ration known as field ration K is available. This consists of concentrated foods sufficient for three meals, packed in cartons. It contains meat or cheese, biscuits, candy, sugar, cigarettes, chewing gum and a dehydrated beverage.

These diets are supplemented by vitamin concentrates when necessary. In this manner we have succeeded in avoiding serious outbreaks of scurvy, beriberi, pellagra or other well defined deficiency diseases. There are, however, reports of mild deficiency states in front line troops who have been on short rations for extended periods of time. Such individuals are quickly restored to health and vigor by adequate rest and food.

GASTROINTESTINAL INFECTIONS

Typhoid, the paratyphoid fevers, the dysenteries and diarrheas, and in some areas cholera have long been the scourge of armies. In 1905 the Japanese were able to effect a reasonable control over these infections during the Russo-Japanese War. Compulsory vaccination against typhoid was introduced into the United States Army in 1911, and a triple typhoid vaccine was used during the first world war. In that conflict typhoid, which had caused disgracefully high rates during the Spanish-American War, was unimportant. There were only 1,386 cases and 215 deaths among our troops. The paratyphoid fevers caused 175 cases and 11 deaths. During the subsequent twenty years of peace these infections were practically eliminated from the Army.

It is a pleasure to be able to report that during the recent period of mobilization and war there has been no increase in the typhoid-paratyphoid rates in spite of the insanitary conditions to which the troops are frequently exposed. Undoubtedly this good showing has been due in part to the effective methods used for providing troops with safe food and water. However, a most important factor has been the program of universal immunization with a triple typhoid vaccine. This vaccine contains killed typhoid bacilli and the paratyphoid bacilli A and B. It is given on induction in three doses of 0.5, 1 and 1 cc at intervals of one week and is repeated before the soldier goes to a theater of operations.

When one considers the dysenteries and the infectious diarrheas the picture is not quite so encouraging. There have been, and there will probably continue to be, sharp but small and well localized outbreaks of such infections.

These diseases are most prevalent during the warm summer months and among troops living in the field. Here the trinity of feces, fingers and flies easily accomplishes its unholy work. As a rule the prevalence of enteric diseases among troops is an index of the sanitary and hygienic discipline of the organizations concerned. Obviously, military situations may arise that will make the maintenance of a satisfactory state of sanitation extremely difficult, but the educational program of the Medical Department is resulting in an increasing appreciation by both line officers and men of the importance of adhering strictly to the principles of sanitation. It is believed that eventually the Army as a whole will look on the occurrence of such filth diseases in a command as a reflection on the efficiency of the commanding officer.

During World War I there were 87,774 cases of dysentery and diarrhea among American troops, and the average time lost from duty was approximately eleven days for each case. The admission rate for 1917-1918 was 18.45 and that for the ten year period from 1930 to 1940 was 1.8. The rate for the last two years has been 10.19. Thus the incidence of the diarrheal diseases since January 1941 has been less than during World War I but greater than during the last ten years of peace. If we are to reduce this incidence further, still greater emphasis must be placed on the training of all military personnel in sanitation and on the supervision and inspection required to see that sanitary matters are handled efficiently. Where this is done the diarrheal diseases will not seriously interfere with military operations.

TABLE 1—Pathogenic Organisms Responsible for Outbreaks

Flexner dysentery bacilli	48 outbreaks
Staphylococci	31 outbreaks
Salmonella organisms	12 outbreaks
Miscellaneous	6 outbreaks
Shiga dysentery bacilli (3 cases)	1 outbreak

Since April 1942 the Preventive Medicine Division of the Office of the Surgeon General has collected data on 320 outbreaks of diarrhea, of which 255 occurred at home and 73 abroad. These outbreaks, which affected groups of soldiers ranging in size from a squad to a division, averaged 75 cases per outbreak, making a rough total of 24,600 cases during the period. In 169 of the outbreaks laboratory studies were made, and 95 outbreaks were reported as due to the pathogenic organisms listed in table 1.

Much excellent laboratory and epidemiologic research has been carried out by Army laboratories and by the Board for the Investigation of Epidemics. Fortunately, certain of the newer sulfonamide drugs including sulfaguanidine, succinylsulfathiazole and sulfadiazine are being used effectively in the treatment of the diarrheal diseases. However such infections still constitute one of the most formidable hazards to be encountered by American troops, ranking second only to malaria in certain tropical theaters. Those of you who join the armed forces should see that there is developed within your organization such a high state of sanitation and sanitary discipline that you will never experience the embarrassment of having to apologize for an epidemic of intestinal disease.

RESPIRATORY DISEASE

The most important diseases encountered during the last war were those transmitted through the respiratory tract discharges by personal contact. Certain of these,

Chart 4—Incidence of respiratory diseases rate per thousand per annum U S Army in the continental United States April 1917 to December 1919 and from April 1940 to December 1942 (U S Army Medical Museum neg No 74097)

including influenza, the common cold, the pneumonias, diphtheria, scarlet fever, measles, mumps and meningitis occurred in epidemic form.

Three of the respiratory tract diseases, namely influenza, bronchitis and pneumonia, were responsible for over a million admissions to hospital and 44,000 deaths. This represented one third of the total admissions for disease and 80 per cent of the disease deaths. Influenza alone caused about 800,000 admissions and 24,600 deaths. Our tragic experience with the pandemic of influenza in the last war left an indelible impression on the older generation of physicians and medical officers. In spite of the increased knowledge of the etiology of this disease and the possession of new but untried weapons for combating it (vaccines and the sulfonamides), influenza is still regarded as potentially one of the most formidable of the disease enemies of the soldier.

The present situation as regards respiratory diseases in the Army is indicated by the graphs in charts 4, 5 and 6 comparing the present morbidity and mortality

rates with those for the last war and with those for the decade of peace which preceded the present war.

In chart 4 there is shown the monthly admission rates for respiratory diseases among troops in the United States from April 1917 to December 1919, also the

Chart 5—Deaths respiratory disease rate per thousand per annum U S Army in the continental United States, April 1917 to December 1919 and after April 1940 (U S Army Medical Museum neg No 74097)

corresponding rates from April 1940 to December 1942. Except for the peak in the fall of 1918, caused by the influenza pandemic, the two curves are somewhat similar, but, in general, conditions have been better during the present war. An outbreak of mild influenza which occurred in the early part of 1941 produced relatively high admission rates, but subsequently the curve has shown only the expected seasonal variations.

The respiratory disease death rates during corresponding periods of the two wars are strikingly different, as is shown on the semilog graph on chart 5. At only one point has the maximum death rate for the present war reached the height of the lowest rate experienced during the last war. This maximum death rate of 0.24 per thousand per annum is about one five hundredth of the maximum death rate of 100 reached at the peak of the 1918 epidemic of influenza.

Chart 6—Admissions for respiratory diseases in the U S Army. Monthly admission rates per thousand per annum since January 1941 compared with the high, low and mean of such rates during ten years or peace (1931-1940)

In chart 6 monthly admission rates for respiratory diseases during the present war are compared with the high, low and mean admission rates by months for the ten year peacetime period from 1931 to 1940. During the spring of 1941 the widespread epidemic of mild

permanent stations, even in our tropical possessions. By the execution of an extensive mosquito control campaign it has been possible to maintain this good record in the United States. In 1941 the Army's mosquito control program in this country cost about 2 million dollars and the malaria admission rate was 18 per

Chart 12—Monthly malaria rates U. S. Army continental United States since 1941 as compared with 1917, 1918 and 1919. Total admissions per month per annum. Rates for 1942 are provisional based on weekly statistical reports. Surgeon General's Office, Division of Preventive Medicine.

thousand. In 1942 the cost was over 3 million dollars and the malaria rate was only 0.6 per thousand. This was the lowest rate ever recorded for the Army. This campaign was supplemented by the extramilitary mosquito work of the U. S. Public Health Service. The results are indicated in chart 12.

We cannot hope for similar results among troops fighting in active tropical theaters, for in such places permanent mosquito control measures cannot be carried out. Unfortunately there is no vaccine against malaria. Either quinine or atabrine may be used as prophylactics under certain conditions in the field. However, these drugs are not real prophylactics as they do not prevent infection but simply delay the appearance of clinical symptoms during their use. Therefore the field control of malaria must be based primarily on sanitary precautions which protect individual soldiers against infected mosquitoes. For this purpose we now possess two excellent new weapons. One is a highly effective

Chart 13—Venereal disease, United States Army, since 1820. Annual rates per thousand strength.

repellent which, after application to the skin, keeps mosquitoes away for hours. The other is a special aerosol spray which is used for the destruction of adult mosquitoes in dwellings. One of the greatest medical contributions that could be made to this country at present would be the discovery of a really effective agent for the prevention of malaria in the field. An intensive research program

directed toward finding such an agent has been under way for several years, and promising drugs are now undergoing field trial.

VENEREAL DISEASES

The mass hysteria that affects men and women during periods of war usually leads to an increase in venereal infections not only in the military but also in the civil population. In chart 13 there is shown the incidence curve for venereal diseases in the United States Army for more than a century. This is the most extensive record of venereal diseases available in this country. It will be noted that these diseases increased during each of our previous wars.

As indicated in the chart, voluntary prophylaxis and instruction in sex hygiene were introduced in 1909, compulsory prophylaxis and forfeiture of pay in 1912, and official recognition of the responsibility of the unit commander for venereal infections in 1922. Not shown are the abolition of compulsory prophylaxis in 1939 and the greater emphasis now placed on the education of troops and the elimination of unwholesome conditions in the vicinity of army camps and stations.

Chart 14—Admissions for disease in the U. S. Army. Monthly admission rates per thousand per annum since January 1941 compared with the high, low and mean of such rates during ten years of peace (1931-1940). Preventive Medicine Division, Office of the Surgeon General.

When mobilization began in 1940 it was expected, because of past experience, that the Army would again experience an increase in venereal diseases. Although more effective control measures had been applied to the civil population during the preceding decade and knowledge concerning these diseases had greatly improved, no one with experience in this field believed that the Army could escape a definite increase in the venereal disease rates.

The mobilization for the present war was accompanied by an increase in venereal diseases, but this increase was insignificant compared with the past. The annual rates for 1940, 1941 and 1942 were 42.5, 40.5 and 37.7 respectively. Not all of the recent slight increase in rates has represented an increase of venereal diseases within the Army. From one fourth to one third of the cases reported have been acquired before the soldier dons his uniform. If one eliminates the cases acquired prior to entry into the Army, the rate for the past four months is only 29 per thousand per annum. Thus it appears that the rate of infection after entry into active service compares favorably with that which existed prior to the beginning of mobilization. It is of interest to

note that in no month of the current war has the venereal rate for troops in this country been as high or anywhere near as high, as the lowest monthly rate for the last war. This should be a source of comfort to those who have been misinformed as to the incidence of venereal disease among the troops. There are reasons for believing that the rate of infection is not substantially different from that which prevails among comparable civilian groups.

Many factors have doubtless contributed to this record of success, though it is impossible to evaluate their relative importance. Specially trained venereal disease control officers have been placed in key positions in this country and overseas. Close collaboration has been developed with civil authorities in the repression of prostitution and the discovery and treatment of sources of infection. Better drugs have improved treatment and shortened the time lost from active duty. Improved prophylactic facilities have been provided.

TABLE 2—Comparison of the Annual Admission Rates in Troops in the Continental United States and Overseas Theaters
1942 Admission Rates (per Thou and per Annum)

	All Causes	Disease Only	Injuries	Respiratory Diseases	Venereal Diseases	Dysentery Diarrhea	Malaria
Continental United States	755	664	91	227	37	7.15	0.6
Theaters in temperate regions							
A	810	668	152	247	6.3	4.7	
B	510	664	146	240	3.4	1.7	1.0
C	793	639	109	297	37.0	16.9	
D	488	408	80	94	9.7	14.9	0.67
Theaters in tropical and subtropical regions							
E	1,111	926	185	97	7.7	107.0	47.0
F	1,011	833	178	154	33.1	60.1	53.5
G	958	852	106	115	61.0	15.6	106.0
H	1,125	1,049	79	143	66.0	117.0	173.0
I	1,221	1,091	130	232	34.0	200.0	33.0

All soldiers are being instructed regarding the hazards of these diseases. Recreational facilities have been provided within the camps, and public spirited civil agencies have provided healthful entertainment in the cities. All of these factors have contributed to the production and maintenance of the present favorable venereal disease situation in the Army.

The present morbidity and mortality rates for all diseases in the United States Army in this country are indicated in charts 14, 15 and 16. In chart 14 the present monthly rates are compared with the high, low and average rates for the peacetime period from 1931 to 1940. In charts 15 and 16 the monthly morbidity and mortality rates for the present period of mobilization and war are compared with those for the comparable period during World War I. It will be noted that there is a difference in the incidence rates for the fall of 1918 and the fall of 1941. However, the contrast between the death rates is pronounced throughout the entire period and it is obvious at a glance that the mortality from disease in this war is much lower than ever before.

HEALTH CONDITIONS IN OVERSEAS THEATERS

Realizing that all of you would probably like to know more about health conditions in our overseas theaters, especially in the areas where we have been engaged with the enemy, I have prepared a table (table 2) in which

Chart 15—Admissions all diseases rate per thousand per annum U. S. Army in the continental United States April 1917 to December 1919 and from April 1940 to December 1942. Preventive Medicine Division Office of the Surgeon General.

the annual disease rates for various theaters are compared with the disease rates among the troops at home. For reasons of security, no strengths or names of places are indicated.

In general, it may be said that the health of the army overseas has been satisfactory. The disease rates in all temperate zone theaters compare favorably with the rates for troops in the continental United States. In some regions they are actually lower than at home. As it might be expected, the tropical theaters show a greater prevalence of malaria, diarrhea and dysentery, and the incidence of these diseases is usually highest among troops who are engaged in combat areas.

Chart 16—Deaths all diseases rate per thousand per annum U. S. Army in the continental United States April 1917 to December 1919 and after April 1940. Preventive Medicine Division Office of the Surgeon General.

It is hoped that this excellent health record established by the United States Army in this war will be maintained and improved. If this is done the Medical Department and the medical profession will have made their contribution to the winning of the present war.

INTENSIVE HUMAN SERUM TREATMENT OF BURN SHOCK

AND A MODIFIED FORMULA FOR CALCULATING THE AMOUNT OF INFUSION

D. L. PRESMAN, M.D.
MARION JANOWA, M.S.
R. E. WESION, M.D., PH.D.
S. O. LEVINSON, M.D.
AND
HEINRICH NECHELES, M.D., PH.D.
CHICAGO

On the basis of recent clinical experience we have become convinced that the usual plasma or serum therapy of burn shock is inadequate and that all the formulas recommended for computation of fluid replacement understate the amounts required in extensive burns. Following burns, the body is severely depleted of fluid and protein, and a large part of the infused protein solutions is utilized to replenish the protein and water reserves. This must be taken into consideration in the estimation of the quantity of material to be infused.

We have previously reported¹ that a boy with more than two thirds of the body surface seriously burned was treated with what we then considered adequate fluid and proteins. During the first twenty-four hours 1,250 cc of normal human serum and 2,000 cc of 0.9 per cent saline and 5 per cent dextrose solution were infused. On the third day there developed a generalized edema which we now believe was due to the administration of inadequate amounts of colloidal and excessive amounts of crystalloid solutions during the first two days. We therefore treated the next severely burned patients with such quantities of normal human serum as were needed to maintain normal blood concentration and plasma volume, disregarding the recommended rules for calculating the amounts of fluid necessary. Following this procedure we feel that in severe burns the infusion of iso-osmotic serum in amounts greater than the original normal plasma volume of the patient sometimes may be required. In addition to studying the loss of proteins from the burned surface and its relation to the blood proteins we also compared the protein content of the blister fluid with that of plasma withdrawn at the same time, a procedure which apparently had not been used before.

The pathologic physiology of burn shock has been reviewed recently by Harkins.² We wish to emphasize, however, that besides leakage from capillaries in the burned area and in the tissues surrounding it there may be a considerable loss of fluid and of protein from the blood due to secondary changes in capillary permeability in other areas of the body. In animal experiments we have seen that scalding of a very small portion of the body surface is usually followed by degrees of hemoconcentration which cannot be explained by local loss of fluid into the scalded area.³

Two cases of severe burns involving 45 to 50 per cent of the body surface are reported here, not as reports of successful treatment but to demonstrate the loss of body water and of protein involved and to establish criteria for effective treatment. Three other cases will be mentioned later in the paper.

THERAPY OF EXTENSIVE BURNS

The patients were brought to the emergency room immediately after the burn, which occurred in the vicinity of the hospital. Morphine was administered. Intravenous therapy with normal human serum was started immediately while clothes were being removed, sterile sheets were applied and the burned surfaces were cleaned and debrided. Sterile petrolatum, sulfathiazole ointment, pressure bandages and warmth were applied. Oxygen by nasal catheter was given for forty-eight hours. Adrenal cortex extract was injected intravenously, mainly for maintenance of the blood chloride levels. Both patients made an uneventful recovery. At no time did blood pressure, pulse or temperature become dangerously abnormal. The administration of normal human serum was not accompanied by reactions. Although 1 patient had a short chill during one infusion, we do not feel that this was caused by the serum, because handling or exposure of the patients resulted in chills. Both patients were white men, one aged 52 weighing 71.7 Kg and the other 27 weighing 55.4 Kg. The percentage of body surface with second degree burns was 45 in patient 1 and 50 per cent in patient 2 (estimated by Berkow's formula⁴). Total blood volume was calculated as one thirteenth of the body weight and plasma volume as 55 per cent of the blood volume. Thus patient 1 had a blood volume of 5,515 cc and a plasma volume of 3,033 cc, the corresponding values for patient 2 were 4,261 and 2,344 cc. Hemoglobin was determined as acid hematin with a photoelectric colorimeter, total protein and albumin by the micro-Kjeldahl method of Ma,⁵ nonprotein nitrogen by direct nesslerization⁶ and hematocrits with Wintrobe tubes, centrifuged for one hour at 2,500 revolutions per minute. Normal human serum containing approximately 7.5 per cent protein was infused.

OBSERVATIONS

Each patient received 1,750 cc of normal serum during the first four hours after the burn, so that the hematocrit values at this time were at approximately normal levels. Yet during the next sixty-four hours (i.e. sixty-eight hours after the burn) both patients manifested a persistent tendency toward hemoconcentration which necessitated additional infusions. During this process of hemoconcentration blood pressures did not change appreciably and gave no reliable index of the patient's condition. Each patient required an additional 2,500 cc of serum during this period plus 6,000 cc of a 0.9 per cent saline, 5 per cent dextrose solution to overcome the continued tendency toward hemoconcentration. In addition, fluids were given by mouth, beginning twenty-five and twenty hours after the burn respectively.

Each patient during the first twenty hours after the burn received an amount of serum in excess of his calculated plasma volume, namely, 107 per cent in

patient 1 and 128 per cent in patient 2. During the sixty-eight hours following the burn each patient received a total of 4,250 cc of serum, i. e., patient 1 received 140 per cent and patient 2 received 181 per cent of his calculated plasma volume as serum infusion (tables 1 and 2). In terms of calculated blood volume, patient 1 received 77 per cent and patient 2 received 100 per cent of serum intravenously.

The question arises as to what happened to the fluid and proteins infused. The disposition of the water can be explained in part by the direct effects of heat,

sustained. Patient 1 received a total of 19,970 cc of fluid intravenously and by mouth during the sixty-eight hours following the burn, i. e., approximately 7,000 cc in twenty-four hours in excess of normal requirements. There was no indication, in either of the 2 patients, that the fluid taken by mouth was not absorbed, because stools were of normal consistency. We have to assume that fluid losses had depleted the body water—intravascular and extravascular—to such a degree that the large volumes of serum, saline and dextrose solutions, plus fluid by mouth, were necessary to reestablish a

by the loss in the burned areas, by exudation from the burned surfaces (which was considerable in both patients), by loss with urine (urinary secretion was not diminished in either patient), by perspiration and by respiration. Furthermore during the first twenty hours the patients did not take fluids by mouth. Since the daily intake of fluid necessary to replace the natural losses of water in a normal adult is approximately 3,000 cc, the patients had received about 22 to 25 per cent more than the normal fluid requirement in the first twenty hours after the burn. This surplus, however, was not sufficient to counterbalance the losses

normal fluid balance. All of this demonstrates the grave needs of the burned organism for isotonic fluids⁸ and suggests the inadvisability of using concentrated plasma or serum, which has been found to be either inferior to iso-osmotic serum or plasma⁹ or deleterious¹⁰ in the treatment of shock in experimental animals.

A similar calculation for patient 2 shows that he received 22,540 cc of fluid by mouth or intravenously during the sixty-eight hours following the burn, i. e., about 7,955 cc in twenty-four hours. This is approxi-

⁸ Collodial fluids must be used until the acute shock syndrome is overcome.

mately an excess of 5,000 cc over the normal requirements for each twenty-four hours, or an excess of 14,000 cc for sixty-eight hours

It is not improbable that both patients would have died from the extreme depletion of circulating plasma and extravascular fluid without the massive intravenous serum therapy that they received

The movements of blood proteins following the burn were as great as those of water. We know from the literature¹¹ and from our own experience with shock in the dog¹² that fluid and protein shifts can occur rapidly after incisions. The plasma proteins of both patients were at or slightly above normal levels at four hours after the burn when the patients had received 1,750 cc of serum. After that the levels dropped, although a 7.5 per cent protein solution (serum) was being administered. This may be due in part to the drawing into the circulation of extravascular fluid which has a lower protein content than that of the blood, and to a shift of intravascular protein out of the circulation.¹³ Each patient received a total of 319 Gm of protein in the form of serum during the first sixty-nine hours after the burn. The estimated normal total plasma protein (7.5 per cent) was 227 Gm for patient 1 and 176 Gm for patient 2. Thus patient 1

In the 2 cases the fluid was collected one-half hour after the burn, before any therapy had been instituted. In the third case studies were done on the fifth day following the burn, after the patient had received 4,250 cc of serum and a high protein diet. In all 3 cases simultaneous determinations were done on the blood plasma.

In all 3 cases the concentration of albumin in the blister fluid was about 80 per cent of the albumin concentration in the blood plasma with slight variation in the individual cases, namely 79 per cent, 81 per cent and 83 per cent. The concentration of the globulin in the blister fluid, however, varied considerably, with values of 44 per cent, 72 per cent and 54 per cent of the concentration in the blood plasma. This variation in the globulin content resulted in a very decided difference between the albumin-globulin ratios of the blister fluid proteins and those of the plasma proteins. In all 3 cases, however, the albumin-globulin ratio of the blister fluid was greater than that of the blood plasma, the actual percentage differences being 179, 112 and 155. The average total protein concentration of the blister fluid was approximately 71 per cent of the plasma proteins with individual values of 65 per cent, 77 per cent and 71 per cent.

TABLE 3—Protein Concentration of Blister Fluid

received 92 Gm and patient 2 received 143 Gm more than the calculated normal total plasma proteins. The movements of proteins out of the circulation must have been very rapid. One must assume, therefore, that following burns proteins at first are drawn into the circulation, but that when protein solutions are infused the body replaces the depleted tissue protein stores promptly and rapidly. It is important also to consider that, although both patients were on a high protein and vitamin diet after the third day, on the thirteenth day and tenth day respectively the plasma protein concentrations were only 5.2 and 4.8 per cent respectively. We wonder whether absorption or utilization of the ingested food proteins was impaired. The urines of both patients contained traces of albumin for a few days after the burn.

On the twelfth day a considerable degree of anemia was present in the patients, suggesting the desirability of administration of whole blood.¹⁴

STUDIES ON BLISTER FLUID

For the study of blister fluid from burns, 3 subjects were employed in whom approximately 5, 10 and 45 per cent of the body surface had been burned (table 3).

11 Beattie, J. Lancet 2: 445 (Oct. 17) 1942. Beattie, J., and Collard, H. B. Brit. M. J. 2: 507 (Oct. 31) 1942. Harkins, S. O., to be published.
12 Weston, R. E., Janota, Martha, Necheles, Heinrich, and Levinson, S. O., to be published.
13 Beattie, J. Whipple 10.
14 See also Lambret, O., and Driessens, J. Rev. de chir. 75: 319 (May) 1937.

It is of interest to note that the concentration of globulin and of albumin respectively in the blister fluid, as compared with the plasma levels, seemed to vary independently. Thus in case 4, in which the blister fluid albumin concentration was 79 per cent of the blood plasma, the globulin in the blister fluid was 44 per cent of the blood plasma. In case 2, in which the blister fluid albumin concentration was 81 per cent of the plasma level, the blister fluid globulin was 72 per cent of the blood plasma. These differences are probably due to varying degrees of capillary damage produced in the different patients or in different areas of blister formation in the same patient. With lesser degrees of capillary damage, principally the smaller albumin molecules may be lost, and with greater damage more of the larger globulin molecules may escape from the vessels.

COMMENT

It must be assumed that during the first twenty-four hours after a burn a large quantity of protein and water is lost in the burned area and possibly also into other tissues of the body from generalized capillary leakage and that, at the same time, extravascular fluids with low protein content are drawn into the circulation to compensate for this loss. It is difficult, therefore, to make more specific calculations of individual shifts without having pre-burn control values and complete plasma volume studies. We know from experimental and histologic evidence that the body has limited

reserves of proteins which can be utilized somewhat during shock¹⁵ or other emergencies¹⁶. Moreover, we know that loss of plasma from burns can be considerable and can exceed the amount normally present in the blood before the burn.

Blalock has shown that in dogs with only one third of the body surface burned an average loss of 57 per cent of the blood plasma occurred.¹⁷ Keeley, Gibson and Pijoan found a reduction of plasma volume in burned dogs varying from 20 per cent to 60 per cent.¹⁸ Since there is little loss from the cutaneous surface of burned dogs these values may be too low for human beings.

Underhill, Fisk and Kapsinow¹⁹ found that the edema fluid in rabbits with one sixth of the body surface burned varied from 3 per cent to 70 per cent of the total blood volume, usually from 20 per cent to 40 per cent. One rabbit lost 70 per cent of its original blood volume. By analogy, in extensive burns in human beings this would amount to a loss of fluid in excess of the total amount of circulating plasma. Harkins² performed numerous similar experiments.

In the case of human burns, Black⁹ employed direct measurement of blood volume in 2 cases. In 1 case with 12 per cent of the body surface burned there was a calculated loss of 2100 cc of blood plasma. In another case with a third degree burn involving only 7 per cent of the body surface there was a calculated loss of 1,218 cc of blood plasma. These 2 patients suffered a plasma loss of 175 cc and 174 cc respectively for every per cent of body surface burned.

Elkinton, Wolff and Lee²⁰ using a rather complicated formula to calculate plasma loss from observed hematocrit and plasma protein, cited cases in which 40 cc, 48 cc, 54 cc and 75 cc of plasma were lost for each per cent of the body surface burned. Tenery²¹ cited 1 case in which 100 per cent of the body surface was burned, a hematocrit value of 71 per cent one hour after the burn indicated a loss of approximately one half the plasma volume. This figure seems to be too low. Black⁹ devised a formula based on observed hemoglobin as compared with the normal hemoglobin and normal plasma volume. This formula is unreliable because of wide variations of normal values for hemoglobin and plasma volume.

Since the acute pathologic physiology of burn shock is largely, if not to its greatest part, due to loss of plasma-like fluid from the blood it follows that the logical therapy consists in adequate replacement of this fluid. Consequently infusions of plasma or serum in large enough quantities to prevent the effects of the oligemia are indicated. In man, it would seem the amount of fluid and protein lost is largely dependent on the extent of the body surface burned. Any formula for fluid replacement should be based on this factor primarily. Changes in hematocrit, hemoglobin and plasma protein concentration cannot be used as sole guides as to the quantity of serum or plasma required, because the normal values before shock are usually unknown and because these values are highly variable. The factor of protein and fluid reserves is highly

variable too and also weakens the use of these determinations as satisfactory criteria of shock.

Harkins has devised a simple formula based on hematocrit values, namely 100 cc of plasma for every point that the hematocrit is above normal. As a first aid formula he suggested giving 50 cc of plasma for each per cent of body surface burned. Of the many formulas suggested those of Harkins are the simplest and least conducive to error in rapid calculations during emergencies. In the case of the first formula we suggest the use of a low "normal" hematocrit value rather than a high one because in anemia a "normal" value actually may be abnormal. The second formula provides too little plasma for extensive burns, according to our experience.

In terms of percentage of body surface burned, patient 1 received during the first forty-eight hours after the burn 89 cc and patient 2 75 cc of serum for every per cent of body surface burned. The greater part of these infusions were given at four and at twenty hours after the burn. We suggest therefore that, following severe burns in adults for every per cent of surface burned 50 cc of serum be given immediately and, in addition, 20 to 30 cc during the first twenty-four hours and another 20 to 30 cc during the next forty-eight hours. Additional crystalloid fluids should not be given during the first twenty-four hours after the burn and fluids and a high protein diet by mouth should be given as soon as the patient is able to take food.

The foregoing doses of serum should be recognized merely as working doses, and if a satisfactory response is not obtained increased amounts should be given. It is far better to administer too much serum or plasma than too little. To restore comparable amounts of protein approximately 16 per cent more plasma than serum must be given, because of the dilution of plasma with citrate solution.²² If there is vomiting, the additional fluid thus lost must be replaced by saline solutions. If large infusions have to be given, as in our patients, we prefer serum in order to avoid the administration of excessive amounts of sodium citrate. The latter may produce hypocalcemia and tetany.

Elkinton, Wolff and Lee²⁰ maintain that, following a burn, the damaged capillaries do not regain their normal permeability for at least thirty-one to forty hours, so that only small transfusions of serum or plasma should be given during this period. They claim that most of the administered protein and fluid would be lost as quickly as they are given. This is true to a certain extent but appears to be a stronger argument for early large transfusions because assuming that a certain percentage of administered plasma or serum continues to leak through the damaged capillaries giving massive doses would mean a retention of a larger total amount of protein and fluid in the blood.

With present local treatments of the burned area the fluid loss from the cutaneous surface and the burned tissues is limited by an eschar and pressure dressings. Therefore with increasing amounts of serum or plasma a greater proportion of the administered fluid would be retained in the blood stream.

The continued loss of plasma through the damaged capillaries besides the reduction in the volume of circulating plasma produces a depletion of the body reserves of protein and fluid. Administration of large doses of

22. Usually 50 cc. of 4 per cent citrate solution is added to 100 cc. of blood. Assuming a plasma content of blood of 55 per cent this would mean that 325 cc. of a solution containing 2.5 cc. of plasma and 1.5 cc. of citrate solution would be obtained after processing.

serum or plasma within the first twenty-four hours would prevent depletion of the body proteins and thereby might protect vital organs like the liver and kidneys. The satisfactory kidney function and the absence of jaundice in our patients point in this direction.²³

It should be pointed out from our experience in cases of critical shock that infusions should be given at a rapid rate (100 cc a minute). A large size needle or even two needles in two veins should be used.²⁴

SUMMARY AND CONCLUSIONS

The usual serum or plasma therapy of acute extensive burns has been found to be inadequate.

Serum or plasma therapy must be given from the point of view of restoring a normal blood volume and not by units of fluid.

Our data and clinical observations definitely indicate the need for much larger doses of serum or plasma in the treatment of burn shock than are provided by the common formulas. By far the greater part of the fluid should be administered during the first twenty-four hours.

We suggest in the treatment of extensive burns in adults the immediate administration of 50 cc of serum (or 60 cc of plasma) for every per cent of body surface burned, and, in addition, 20 to 30 cc for every per cent should be administered during the first twenty-four hours and another 20 to 30 cc in the first seventy-two hours following the burn. Total administration, therefore, should be at least 100 to 110 cc for each per cent of body burn. Crystalloid fluids should not be given during the first twenty-four hours. Fluids and a high protein diet by mouth should begin as soon as possible.

Simultaneous analyses of blister fluid and of blood plasma have been performed. Blister fluid contains a concentration of proteins equivalent to 70 to 80 per cent of the plasma proteins. The albumin content of blister fluid was fairly constant, but the globulin content showed decided variations independent of the albumin or globulin values of the blood and of the albumin values of the blister fluid.

A Necessary Step Toward Emotional Stability—The student who faces the college adjustment while still dependent on and closely identified with his family—and most students are—has a special handicap in all the phases of his development. Before he can fit into the college environment altogether successfully he must complete the changes which are expected to occur in the family relationship as the individual grows up. If the student can be properly assisted in handling these problems he may be saved much emotional distress and prevented from wasting energy which can be used more profitably elsewhere. For detachment from the family is a necessary step toward the emotional maturity of an individual, it is a prerequisite to the smooth development of other growth process.

Detachment from the family does not imply antagonism to it or a complete denial of its participation in the individual's life. And in the achievement of detachment, parental guidance need not be thrown off abruptly or ignored. As the phrase is used here, the development of independence means not a severance of all relations between the growing individual and his family but the gradual establishment by the individual of habits of independence in choosing his goals, his values and his associates—Fry, Clements C. *Mental Health in College*, New York, Commonwealth Fund, 1942.

THE THERAPY OF BACTERIAL ENDOCARDITIS WITH MASSIVE DOSAGE OF SULFADIAZINE

REPORT OF FOUR CASES

EDGAR HULL, MD

ROBERT H BAYLEY, MD

AND

ALICE B HOLOUBEK, MD

NEW ORLEANS

Recently Dick¹ reported the recovery of a patient with bacterial endocarditis to whom a massive dose of sodium sulfadiazine was administered. This is a report of 4 cases in which similar therapy was employed.

CASE 1—A white woman aged 36 had been having fever daily for five weeks before her admission to the Hotel Dieu on Sept 21, 1942, the highest temperature each day being from 101 to 103 F. One week before admission she had experienced sudden pain in the left infra-axillary region, aggravated by deep breathing. She gave no history of rheumatic fever or of preexisting heart disease.

She was in good general condition. The blood pressure was 130 mm of mercury systolic and 50 diastolic. The pulse approached a water hammer type. The heart was moderately enlarged. Blowing systolic and diastolic murmurs were audible over the base of the heart. The lungs were normal. The spleen was considerably enlarged, the tip extending about 5 cm below the rib margin on deep inspiration. No petechiae were seen. Fever was present every day before treatment was begun, the daily peaks varying between 101 and 103 F.

Red blood cells numbered 3.34 million on admission, leukocytes 7,000 and hemoglobin 10.5 Gm. The urine contained a trace of albumin and numerous red cells. Culture of venous and arterial blood yielded a nonhemolytic, nonpigment producing streptococcus on the mediums which were used.

On September 29, 30 Gm of sodium sulfadiazine was given intravenously, after alkalization of the urine by the administration of sodium bicarbonate. Thirty Gm rather than 40 as used by Dick was given because of the small size of the patient (110 pounds, or 50 Kg). Vomiting occurred immediately and was repeated at short intervals for twenty-four hours. The urine became grossly bloody six hours after the drug was given and remained so for three days, microscopic hematuria, present before treatment, continued.

Immediately after the injection the concentration of free sulfadiazine in the blood was 75 mg per hundred cubic centimeters, twelve hours later it was 32, twenty-four hours later 22.5, thirty-six hours later 15, sixty hours later 5 and eighty-four hours later 1.2. On the day following the injection the temperature reached 103 F but did not exceed 100 for seven days thereafter. The patient's general condition seemed unchanged. A blood culture on October 1 was still positive.

On October 4, five days after the initial treatment, 5 Gm of the drug was given intravenously, on October 5, 5 Gm intravenously and 4 by mouth, on October 6, 12 Gm by mouth, and on October 7, 8 Gm intravenously and 6 by mouth. On October 7 the blood concentration had reached 42 mg per hundred cubic centimeters. Treatment was suspended for one day and then resumed, attempt being made to maintain a blood concentration of from 15 to 20 mg per hundred cubic centimeters.

On October 10 petechiae were noted about one ankle. On October 13 severe pain, swelling and tenderness in the left forearm appeared, which was attributed to embolism in the forearm muscles. On this day the blood culture was still positive.

On October 14, because of increasing microscopic hematuria, treatment was suspended for two days. Thereafter sufficient

From the Department of Medicine, Louisiana State University School of Medicine, and the Medical Services of the Charity Hospital of Louisiana at New Orleans and the Hotel Dieu.
1. Dick, George F. Subacute Bacterial Endocarditis. Recs of Following Intravenous Sodium Sulfadiazine, *J A M A* 120 24 (Oct 5) 1942.

sulfadiazine was given by mouth to maintain blood levels of from 14 to 20 mg per hundred cubic centimeters, and hyperpyrexia was induced at two or three day intervals by intravenous injection of typhoid vaccine.

Throughout the treatment, transfusions were given whenever the blood count revealed increasing anemia. On November 3 the red cells numbered 3.9 million, the hemoglobin 11.3 Gm.

After the first week of treatment the patient's condition slowly grew worse. The blood culture remained positive. Two further embolic episodes occurred, one in the muscles of the buttock, the other in the spleen. Daily temperature peaks varied from 100 to 104 F. Therapy with sulfadiazine was discontinued on October 31 and the use of sodium para-aminobenzoate begun. Since there was no favorable response to this drug the use of sulfanilamide in large dosage was begun on November 17. Although the temperature remained practically normal while sulfanilamide was being employed there was no improvement in the general condition of the patient, and death occurred on Dec 7 1942.

Autopsy revealed numerous vegetations on the aortic valve with ulceration through the posterior cusp and secondary involvement of the ventricular surface of the anterior mitral cusp. The vegetations were small and smooth suggesting that partial healing had occurred. There were three large old infarcts in the spleen and two small ones in the right kidney. Acute diffuse glomerulonephritis was also present.

CASE 2—A white man aged 25 was admitted to Charity Hospital on Sept 10 1942 with a chief complaint of fever of twelve days duration. The onset had been insidious and associated with undue fatigue. Five days after the onset the symptoms became more pronounced and his temperature had been observed to vary daily between 99 and 104 F. At this time general malaise was prominent. His general health had been good until the onset of the present illness. He had experienced vague joint pains at the age of 12 years. Two years thereafter he became troubled with recurrent epistaxis and was told by his physician that he had enlargement of the heart. For the next four years he 'took things easy' and throughout has experienced no cardiovascular symptoms.

The patient was well developed and well nourished and not acutely ill. His skin particularly that of his face and hands presented a delicate cream and coffee pigmentation together with moderate pallor. No petechiae were seen. Many teeth were carious, and oral sepsis was present. The cardiac apex impulse was diffuse and of increased torcetulousness and was located in the fifth and sixth intercostal spaces at the mid-clavicular line. A systolic shock was present at the apex, where the first heart sound was greatly accentuated and followed by a 2 plus systolic murmur. A murmur characteristic of aortic insufficiency was audible at the aortic valve area. The rhythm was regular and the blood pressure was 130/45. Neither the liver nor the spleen was palpable.

Blood cultures taken during the first few days following admission were negative but after the second week an alpha streptococcus was consistently isolated.

On the twenty-fourth hospital day (October 3) 40 Gm of sodium sulfadiazine was given intravenously and a high fluid intake maintained thereafter. Through a misunderstanding of orders the blood level was not determined until twenty-four hours later, when it was 25 mg per hundred cubic centimeters. Vomiting occurred immediately after the injection and recurred several times. Gross hematuria appeared within a few hours and persisted for four days, but there was no diminution of urinary output and blood urea remained normal.

On the fourth day following the injection the blood level of free sulfadiazine had declined to 100 mg per hundred cubic centimeters. Subsequent treatment has been substantially the same as that employed in case 1. Sulfadiazine, sulfanilamide and fever therapy, sodium para-aminobenzoate, sulfanilamide. No definite improvement occurred following the initial therapy. The blood culture has remained positive and daily fever persists. The general condition of the patient has remained fairly good owing possibly to inhibition of growth of the organisms by the large amounts of sulfonamide drugs which have been used.

CASE 3—A white woman aged 39 was admitted to the Charity Hospital on Sept 16, 1942 complaining of cough and shortness of breath. She dated the onset of her illness eight weeks previously, with a cold which became progressively worse. Her local physician examined her and told her that she had a bad heart. Her symptoms were progressive, with increasing difficulty in breathing. Her past history revealed nothing of significance.

The patient was well developed and well nourished and her temperature was 100.4 F. There were signs of congestion at both lung bases. The heart was moderately enlarged. There were diastolic and systolic murmurs audible over the base of the heart. The blood pressure was 115/50, the pulse approached Corrigan in type. The rhythm was regular. The liver was enlarged to 2 or 3 fingerbreadths below the right costal margin. The spleen was tender and moderately enlarged (3 to 4 fingerbreadths below the left costal margin). The left ankle was tender, reddened and swollen.

Laboratory examination revealed 7.5 Gm of hemoglobin, 3,100,000 red blood cells and 11,200 white blood cells. The urinalysis was negative except for a trace of albumin. The urea nitrogen was 50 mg per hundred cubic centimeters. X-ray and fluoroscopic examination revealed generalized cardiac enlargement. The venous pressure was 110 mm of water.

The diagnosis of an acute episode of rheumatic fever was considered on admission and the patient was given 1 Gm of sodium salicylate three times daily. The fever and pain, swelling and redness of the ankle responded to this therapy, but the patient became more dyspneic and uncomfortable in spite of full digitalization.

During the first week of hospital stay, petechiae were noted on the lateral aspects of both feet. Flame shaped areas of hemorrhage were visible in both tundi. Increased reflexes with ankle and patellar clonus developed bilaterally. The first blood culture was negative, but ones taken on the 22d and 24th of September were positive for nonhemolytic streptococci. At this time salicylates were discontinued. The patient was first treated with the usual doses of sulfadiazine (4 Gm initially followed by 1 Gm every four hours day and night) for four days, at the end of which time the sulfadiazine blood level was 117 mg per hundred cubic centimeters. The patient's temperature ranged from 100.6 F to subnormal daily.

On the evening of September 30 after confirmation of the diagnosis by positive blood culture 30 Gm of sodium sulfadiazine in 1,500 cc of distilled water was given intravenously, the urine previously having been alkalinized by administration of sodium bicarbonate. The blood level obtained four hours after administration of the drug was 85.4 mg of free sulfadiazine per hundred cubic centimeters of blood. The next morning the blood sulfadiazine level was 63.5 mg per hundred cubic centimeters and the urea nitrogen was 19.0 mg per hundred cubic centimeters. During the first twenty-four hours after administration of the drug, 390 cc of grossly bloody urine was voided. The patient's temperature was normal.

On October 2 the patient was semicomatose and bleeding of the gums was noted. One hundred and sixty cc. of blood tinged urine was voided. The blood sulfadiazine level was 45 mg per hundred cubic centimeters and the urea nitrogen was 33.2 mg per hundred cubic centimeters. A bilateral sympathetic block was done in an attempt to increase urinary excretion. Five hundred cc of blood was given by transfusion. The blood pressure was 148/34 and the pulse was definitely water hammer in character. A blood culture taken on this day showed no growth. The next day ureteral catheters were inserted and 85 cc of bloody urine was obtained. The catheters were left in place and frequent lavage was performed.

On October 4 200 cc. of urine was voided. The next day the catheters were removed no evidence of ureteral blockage being present. No urine was voided during the next twenty-four hour period. The patient's condition was poor and edema was increasing. The blood sulfadiazine level was 22.5 mg per hundred cubic centimeters, urea nitrogen 50, creatinine 5.9 and carbon dioxide combining power 0.8. Blood culture this day was positive less than 1 colony per cubic centimeter of blood.

On October 6 65 cc. of purulent foul urine was voided, and the next day 700 cc. The patient's condition was growing worse. She was comatose and irrational and on October 8

2 This patient died on Jan 4 1943. Autopsy revealed vegetative endocarditis of the aortic and mitral valves and acute diffuse glomerulonephritis.

she was again semicomatose. The blood sulfadiazine level was 20.2 mg per hundred cubic centimeters, urea nitrogen 66.8, creatinine 9.5 and the carbon dioxide combining power 66. Blood culture was tentatively negative. She excreted no urine for thirty hours. The next day 300 cc of urine was obtained by catheterization. Her condition continued to be grave and she died on the morning of October 10. Her temperature had been essentially normal since administration of the sodium sulfadiazine.

Postmortem examination revealed multiple small vegetations on congenitally deformed (bicuspid) aortic valve cusps, one of which was perforated by ulceration. The kidneys were enlarged and reddened and showed no gross areas of infarction. On section, the cortical striations were obscured. In and immediately adjacent to the pyramids were seen light yellowish gray streaks alternating with the deep red of the tissue. The pelvis, calices and ureters were free of crystal formation and of pathologic changes. On microscopic examination the essential lesions were shown to be of the collecting tubules, which were filled with a purulent necrotic exudate with some extension into the surrounding tissue. There were no crystals in the exudate but it did show the same refraction to polarized light as sulfadiazine crystals. The glomeruli were unaffected. In addition there were infarction of the spleen, thrombophlebitis of both ovarian veins and multiple infarction of the lungs.

CASE 4—A white youth aged 16 years was admitted to Charity Hospital on Sept. 13, 1942 with the complaints of chills, fever and frontal headache of simultaneous onset ten days prior to admission. The symptoms continued and were somewhat less severe after the first week. Occasional vomiting had occurred. On the third day pain developed in the left hip, which was aggravated by exertion. A local physician had given him yellow tablets (probably atabrine), which he had continued to take, one three times a day, until the day of admission. The past history revealed that two years before he had had a febrile illness of three weeks' duration characterized by low grade fever, epistaxis and joint pains. A local physician had pronounced the condition malaria, however, the fever failed to respond to quinine, which was started during the first week. He had had occasional attacks of sore throat and had had an abscess of the right ear three years before. The remainder of the history was noncontributory.

The patient was acutely ill and moderately lethargic. Herpes simplex was present. The skin presented a light yellow tint, although the scleras were white. One petechial hemorrhage was present in the fundus of the right eye and another on the mucous membrane of the lower lip. Examination of the lungs revealed no abnormal findings. The heart was thought to be of normal size. A loud, harsh systolic murmur was present at the apex accompanied by a thrill. The rhythm was regular. The rate was 128 per minute. The blood pressure was 120/78. The spleen and the liver were not felt and the remainder of the physical examination was negative.

The initial laboratory studies showed 4.5 million red blood cells per cubic millimeter in the peripheral blood. The white blood cell count was 10,000 with 98 per cent polymorphonuclear leukocytes. No malarial parasites were found. The specific gravity of the urine was 1.023, and 1 plus albumin was present, together with many pus cells and a few hyaline casts. Urine cultures were negative for organisms of the typhoid group. The blood urea nitrogen was 12 mg per hundred cubic centimeters. The spinal fluid was negative. X-ray examinations of the chest and hip were negative.

During the nine days of hospitalization the temperature remained elevated between 102 and 104 F with occasional peaks to 106 F. Recurrent petechial hemorrhages appeared in the conjunctivas, fingers and toes. Occasional vomiting occurred. The lethargy progressed to stupor after the first week, and it was apparent that the patient could not live more than a few days. At this time venous and arterial blood cultures taken on admission were reported as negative. The diagnosis of bacterial endocarditis nevertheless seemed almost certain and the patient was given 30 Gm of sodium sulfadiazine intravenously dissolved in 600 cc of distilled water following an intravenous infusion of 2,000 cc of isotonic solution of sodium chloride. The blood level twelve hours later was 69 mg per hundred cubic centimeters. At this time the urine had become

grossly bloody, the blood urea nitrogen was 38 mg per hundred cubic centimeters and the carbon dioxide combining power was 40. Sixteen hours after the administration of sodium sulfadiazine the patient died.

Autopsy revealed many small and several large vegetations on the mitral valve. Infarctions of the spleen and kidneys were present, together with countless petechial hemorrhages at all visceral surfaces. No crystals were found in the tubules or calices, and no lesions attributable to sulfadiazine were present. Cultures of the heart's blood and of the vegetations were positive for alpha streptococcus.

SUMMARY

Four patients with bacterial endocarditis were treated with sodium sulfadiazine in massive dosage. All four patients showed gross hematuria following the massive initial dose.

Two patients who were in good condition when treatment was begun showed hematuria as the only significant toxic effect of the drug, but neither patient was cured.

The third patient, who was very ill when the treatment was given, developed suppression of urine and died of uremia eleven days after a single intravenous injection of 30 Gm of sodium sulfadiazine. At autopsy necrotizing nephrosis, involving principally the collecting tubules, was present.

The fourth patient, who was practically moribund when the treatment was given, died sixteen hours after the intravenous administration of 30 Gm of sodium sulfadiazine. No renal lesions attributable to toxic effect of sulfadiazine were present at autopsy.

PANHISTERECTOMY VERSUS IRRADIATION FOR EARLY CANCER OF THE UTERINE CERVIX

HOWARD W. JONES, JR., M.D.

AND

GEORGEANNA E. SEEGAR JONES, M.D.

BALTIMORE

It is the clinical impression of many gynecologists that panhysterectomy offers a satisfactory method of treatment for selected cases of early cancer of the cervix. In the most recent report on cancer of the cervix from the Kelly Clinic,¹ 1 patient with a recurrence after operation was treated for every 10 patients admitted with primary cancer of the cervix. We have reviewed a selected group of 36 cases of early carcinoma of the cervix treated with panhysterectomy and compared the results with 704 unselected cases in all stages, treated with radiation.

It is, however, not a matter simply of comparing gross and absolute cure rates, other factors must be considered. For example, Martsloff² demonstrated with operable material that the microscopic appearance was of importance in determining prognosis. Due consideration must be given to such an essential aspect. We have also reviewed the curability in relation to the microscopic changes in both irradiated and surgically treated patients.

Dr. Richard W. TeLinde helped the authors in this study. From the Kelly Clinic and Department of Gynecology of the Johns Hopkins University and Hospital.

1. Jones, Howard W., Jr. Carcinoma of the Cervix. Clinical Evaluation of Radium Dosage and Supplementary Roentgen Irradiation Based on a Study of 915 Cases. *South. M. J.* 35: 959 (Nov.) 1942.

2. Martsloff, K. H. Carcinoma of Cervix Uteri. A Pathologic and Clinical Study, with Particular Reference to the Relative Malignancy of the Neoplastic Process as Indicated by the Predominant Type of Cancer Cell. *Bull. Johns Hopkins Hosp.* 34: 141 (May) 184 (June) 1923.

The problem has been complicated in recent years by the not infrequent "accidental" finding of exceedingly early carcinoma when there is no real suspicion of it. These "accidental" findings are made by the more common use of biopsy of the cervix. In this group may be included the so-called preinvasive carcinoma,

TABLE 1—*Distribution of Type of Carcinoma*

or Bowen's disease of the cervix. It is obvious that any conclusion which might be reached for the treatment of early cancer of the cervix in general would not necessarily apply to the exceedingly early lesions just mentioned.

MATERIAL AND RESULTS

The irradiated material reviewed in the present study consists of 704 patients with carcinoma of the cervix treated by radium or radium and x-rays at the Kelly Clinic between Oct 1, 1927 and Dec 31, 1935. The details of treatment and other clinical features have been reported elsewhere.¹

The material has been divided into clinical stage according to the League of Nations classification and further subdivided, with the Martsloff classification, according to microscopic appearance of the tumor. The adenocarcinomas have been separated from those of the epidermoid type, which are subdivided into spinal cell, transitional cell and fat spindle cell. The spinal or prickly cell variety is composed for the most part of cells resembling those seen in the superficial zone of stratified cervical epithelium. The cells are adult in character and exhibit their squamous tendencies by the occurrence of cell nest or pearl formation. The cell membranes are distinct, and although they resemble prickly cells the intercellular protoplasmic bridges are

TABLE 2—*The Cure Rate in Relation to Microscopic Abnormalities—704 Cases of Cervix Carcinoma Treated with Irradiation*

Clinical Stage	Spinal Cell Cancer	Transitional Cell Cancer	Spindle Cell Cancer	Adeno carcinoma	Total
1	2/6 (33%)	37/64 (58%)	10/11 (91%)	1/6 (16%)	50/87 (57.5%)
2	3/4 (75%)	33/30 (110%)	8/24 (33%)	4/6 (66%)	50/124 (40.3%)
3	2/9 (22%)	41/180 (23%)	3/4 (12%)	4/9 (44%)	52/240 (21.7%)
4	1/27 (4%)	10/209 (5%)	0/12 (0%)	0/3 (0%)	11/233 (4.7%)
Total	8/46 (17%)	123/543 (23%)	23/29 (79%)	9/30 (30%)	163/704 (23%)

not easily discernible. Mitoses are few. The transitional cell variety is composed of cells resembling the midlayer of stratified cervical epithelium. The cells may have variable shapes and are often round. The cytoplasm is relatively sparse. The spindle cell variety is composed of spindle shaped cells resembling sarcoma. Mitoses are common. The cytoplasm is very sparse and the cells are closely packed.

The distribution in the 704 cases of the present series is shown in table 1.

Table 2 gives the five year cure rate according to the clinical stage and microscopic structure.

The operative material consists of all patients with early carcinoma of the cervix operated on at the Johns Hopkins Hospital during the ten year period 1927-1937. It was the practice of the clinic during that time to operate on a selected number of such patients. This small group consists of only 36 patients. These cases were chosen as suitable for operation in consultation with the gynecologist in charge of radiation therapy.

The 36 cases were distributed as follows: adenocarcinoma 2, spinal cell carcinoma 2, transitional cell carcinoma 30, spindle cell carcinoma 2. The results of treatment are shown in table 3.

COMMENT

The absolute cure rate of 41.6 per cent for the patients operated on does not compare favorably with the cure rate of 57 per cent by irradiation.

Although the results of the surgically treated group are compared in this paper with a series of stage 1 cancers treated with radiation, the superiority of the latter is greater than is indicated by the figures herein quoted. This superiority arises from the fact that the surgically treated group represents lesions with an

TABLE 3—*Cure Rate in a Series of Thirty-Six Selected Patients with Early Cervix Carcinoma Treated with Pouchostriectomy*

Total Number of Patients	Living and Well 5 Years or More	Living and Well 5 Years After Treatment by Radium for Recurrence After Operation	Died	Not Followed	Absolute Cure Rate by Operation per Cent
36	15	2	15	4	41.6

average malignant ulceration of 1 cm (Schmitz 1), while the cancers in the irradiated group are classified as stage 1 League of Nations and therefore represent lesions further advanced than those of the surgically treated group. It would perhaps be more accurate to compare the 41 per cent cure rate by operation with the reported cure rates up to 80 per cent for Schmitz 1 cases.

However, as already stated, the microscopic abnormality is of great importance in determining the prognosis in early cases.

It is impossible to discuss the subject of tumor morphology relative to curability without detailed reference to the work of Martsloff.² He reported the five year survivals, according to microscopic structure in 379 cases of carcinoma of the cervix. Martsloff's cases were divided into adenocarcinoma and three types of epidermoid carcinoma—spinal cell, transitional cell and spindle cell. It should be emphasized that this classification is morphologic and not histogenic. It should also be remembered that the criterion of classification is fundamentally different from the grading of tumors according to the method of Broders. However a rough parallel between the two methods exists: low grade tumors (grade 1 Broders) are for the most part of the spinal cell type while high grade lesions usually correspond to the spindle cell type.

When only operable material was considered and cases presenting unsuspected involvement of the broad ligaments at the time of operation were eliminated, the five year cure rate of patients surviving operation was

found by Martzloff to be adenocarcinoma 75 per cent, spinal cell cancer 47 per cent, transitional cell cancer 24.2 per cent and spindle cell cancer 9.5 per cent. These results were obtained by radical Wertheim operations on carefully selected material.

It would be a misapplication of statistics to apply Martzloff's figures to curability by irradiation. In 1928 Healy and Cutler³ found that by irradiation the curability of carcinoma of the cervix, with respect to the microscopic appearance of the tumor, was the reverse of that obtained by operation, provided cases of similar clinical stage were considered, the best results were obtained in the spindle cell group. These conclusions were based on a study of 200 cases. The investigations of Hueper and Schmitz⁴ and of Pomeroy and Strauss⁵ seemed to confirm these observations of Healy and Cutler, while Plaut⁶ could find no correlations between microscopic appearance and curability. Such investigations have, for the most part, been handicapped by material insufficient for classifying their results by both clinical stage and microscopic appearance.

The more detailed study of the relation of microscopic abnormality to cure rate and method of therapy may best be discussed in a paragraph for each pathologic type.

Transitional Cell Carcinoma—With irradiation a 58 per cent cure rate was obtained. Of the 30 patients with transitional cell carcinomas operated on, 14, or 47 per cent, survived for five years. The difference is undoubtedly greater than that expressed by the percentage, as the irradiated cancers are League of Nations 1 while the operative cancers are Schmitz 1, including 5 preinvasive lesions.

Spindle Cell Carcinoma—There are too few spindle cell cancers in the operative series to estimate the curability in this group. However, it is reasonable to assume that Martzloff's figure of 9 per cent curability would be higher in the Schmitz 1 cases herein considered, as Martzloff was dealing with League of Nations 1 and some 2's. Yet it is difficult to believe that the figure would nearly approach the 91 per cent cure obtained with irradiation, or with comparable figures reported by other observers.

Spinal Cell Carcinoma—The material in the present study contains only 6 spinal cell carcinomas stage 1 treated with radiation and only 2 by operation, so that no conclusion is possible. This is particularly unfortunate, as certain collateral evidence indicates that this might be a favorable group for operation. First, in considering all stages of carcinoma (table 2) irradiation of spinal cell cancers gives the poorest results. This is in confirmation of Healy and Cutler and others. Second, Martzloff obtained the most favorable results by operation in this group. While no conclusion is possible it is true that irradiation has proved more generally satisfactory, all cases considered. So it is apparent that the burden of proof must be put on the advocates of operation.

Adenocarcinoma—Here too there is insufficient evidence for or against operation or irradiation to warrant a conclusion. There is reason to believe that adenocarcinoma is the most favorable group for operation, as indicated by the operative cure rate of 75 per cent reported by Martzloff. It is difficult to believe that irradiation can equal this percentage when comparable clinical material is considered. The problem is complicated by the relatively satisfactory results of many workers with irradiation in adenocarcinoma of the cervix irrespective of the clinical stage (table 2). However, based on Martzloff's results, and until further statistics on group 1 adenocarcinoma have been accumulated, panhysterectomy must be considered a satisfactory method of therapy for this uncommon clinical picture.

Prenvasive Carcinoma—While the present study strongly suggests that operation is not the method of choice in early stage 1 cases, especially in the transitional and spindle cell groups, it does not at all indicate that the "accidental" and preinvasive lesions should not be operated on. In the 36 cases of the operative series herein reported, 5 belong to this group. All these patients are living except 1, who died of postoperative shock. With the information at hand, the question of operation or irradiation cannot be definitely decided for this group.

In a more general consideration of the selection of type of therapy for these early cases of carcinoma of the cervix, it is worth noting that, although the lesion in several instances was thought to be of the earliest, there was found, on examination of the gross operative specimen, a large intracervical nodule of cancer. For this reason, and because of the experience considered in this paper with slightly more advanced squamous cell lesions, we feel that irradiation will prove more satisfactory for the entire squamous cell group, including the "accidentally" discovered and preinvasive lesions. If radium is selected as the method of treatment, full dosage should be employed, because early lesions of the cervix may be more extensive than clinical examination can indicate.

SUMMARY AND CONCLUSIONS

Although irradiation has been demonstrated by numerous observers over a period of years to be more satisfactory than panhysterectomy for the average case of cervix carcinoma, it is the opinion of many gynecologists and general surgeons that operation is a satisfactory method of therapy for very early cases. That panhysterectomy is commonly selected in such cases is indicated by the fact that, in our experience, for every 10 patients with primary carcinoma of the cervix there is 1 admitted for treatment of a recurrence after operation.

During the years 1927-1937, 36 patients with early carcinoma of the cervix were carefully selected for operation at the Johns Hopkins Hospital. In spite of this careful selection a five year cure rate of only 41 per cent was obtained. This does not compare well with the cure rate of 57 per cent obtained by irradiation with less favorable material.

It has therefore been concluded that as a practical therapeutic procedure for early carcinoma of the cervix panhysterectomy is an unsatisfactory method of therapy. Irradiation is the treatment of choice.

DIAGNOSTIC TIME SAVERS FOR
OVERWORKED PHYSICIANS

WALTER C. ALVAREZ, M.D.

ROCHESTER, MINN.

For the duration most of the physicians left to care for the civilian population are going to be terribly overworked. Already many are carrying a killing load, the older men who used to have assistants are now back to taking histories, and many are having trouble because so many of the roentgenologists and laboratory workers who used to help them with their diagnoses have gone to war. More and more, then, the physician who just cannot get around to see all the persons who call for him in a day will have to attend first to those who appear to be seriously ill, he will have to try to make diagnoses as quickly as possible and with the minimum of help from others and he will have to try to recognize immediately and dismiss quickly all those many chronic complainers and psychopathic worriers who would love to take up much of his day with long rambling accounts of their aches and pains. Perhaps he can get some of these persons to look on the sparing of their physician's time as their contribution to the war sacrifice! They are probably too self-centered to return, but one might suggest it to them.

All this, of course, does not mean that any one is advocating the doing of poor or careless work. What is proposed is that we physicians now do more of what we have always done, and that is to try to make the diagnosis with the minimum of expense to the patient and the minimum of effort for ourselves. All physicians cannot practice as does a professor of medicine in a free clinic, ordering all the tests he wants, many of his patients haven't the money to pay for them, others are not concerned enough over their illness to want to pay for them, and many do not need them because the diagnosis can be made correctly without their help.

Every physician worth his salt should be making perhaps more than half of his diagnoses every day without the help of roentgenologic or laboratory reports. Usually he must go on and order some tests, but they will serve largely to confirm his first hunch or to safeguard his reputation or to satisfy the patient who usually looks on him merely as a passive broker who will order tests and then relay the reports! Today it seldom occurs to a much traveled patient that a good clinician can recognize many a syndrome and be sure of it merely from the answers to a few questions or that he can see in a few minutes that he is dealing with a scatterbrained neurotic, a constitutional inadequate, a chronic worrier, a hypersensitive complainer, a fussbudget of a perfectionist or a psychopath. All the average patient in a consultant's office wants today is tests and plenty of them, he wants to "be given the works."

I, who depend on tests day after day, would be one of the last to decry their value, but still I maintain that nowadays hundreds of diagnoses would be made more correctly if the physician concerned were to order fewer tests and ask a few more questions of the patient.

Often when I am trying to get a psychoneurotic woman to see how it was that after a few minutes or talking to her I could be so certain that her troubles were functional in origin I will say, "Let us suppose you were to hear a child cough violently, then whoop and finally vomit, wouldn't you know what it had?"

"Surely," she says, "it would have whooping cough." "Of course, and you would be sure of it, wouldn't you, because you have seen that clinical picture many times before?" You wouldn't feel the need for sending the child for any laboratory tests. All right, then, why can't you see that after years of studying the sick and listening daily to their stories of illness, I ought to be able to recognize a few of the common diseases the minute I hear the well known tale. I ought to know them on sight just as you know whooping cough on sight."

What I wish to do in this paper is, first, to encourage physicians to put greater trust in the diagnoses they make from the history and second, to pass on especially to my younger medical brethren some of the little tricks of diagnosis that I have picked up in the course of forty years. So often when a patient is referred to me for diagnosis I am impressed by the fact that the wise old family doctor, and perhaps my young assistant as well, had the right hunch as soon as they took the history, they felt then that the trouble should all be nervous in origin but when from the laboratories came reports of a slowly emptying gallbladder, some peculiarity in the electrocardiogram or some agglutinins for *Brucella abortus* they lost confidence in their clinical acumen and gave in to the laboratory report. In many such cases they shouldn't have given in because subsequent events showed that their first diagnosis was right. The laboratory finding was usually correct but it wasn't significant. It was like the finding of amebas in the stools of a man who has recently collapsed and quit work because of a slight stroke. In such cases one would like to hear the man's physician say to him "Even if you have amebiasis or the diseased gallbladder that some one says you have that couldn't possibly account for your symptoms, they are those of a nervous breakdown."

HINTS TOWARD THE RECOGNITION OF
FUNCTIONAL TROUBLES

In most cases of neurosis the diagnosis is best made from the recognition of a typical story and not from attempts to exclude organic disease. The trouble with the latter technic is that too often the overhauling turns up some unimportant organic disease, and then, if one hasn't already discerned what the trouble is, one is very likely to be thrown off the diagnostic track.

Good signs of a neurosis are the inability of the patient to say what the main complaint is, a tendency to answer the physician's questions with irrelevant statements, to complain too much of little things, to break in and not let the physician finish a sentence to keep consulting a long written list of symptoms to tremble and weep as the story is told or to tell the physician how to diagnose and treat the disease. The harder it is to get a clear history out of a person, the less likely he or she is to have organic disease.

Certain symptoms practically always mean a neurosis—symptoms such as globus, jitteriness, the fear of not being able to get a deep breath, fluttering or burning in the abdomen, or repeated belching, regurgitation of food immediately or soon after eating, distress or bloating immediately after eating or especially after drinking cold water or "pop," attacks of pain and soreness in the lower abdomen associated with the passage of mucus, abdominal distress which can be avoided or relieved by keeping the bowels open, attacks of abdominal pain following emotional debauches, distresses that come before breakfast, pains that leave no residue or

sores, bloating that comes up during the day and disappears during the night without the passage of flatus, and pains that have survived several abdominal operations.

The wise physician will think also of a neurosis or a neuralgia whenever he hears of a pain that for years has been fairly constant day and night and which does not interfere much with sleep. A long lasting ache in the left upper quadrant of the abdomen, and all those aches which are out in the abdominal wall are usually associated with or due to spondylitis. Pains in the back are usually arthritic in origin and rarely have anything to do with the kidneys. Pains that shift about in the abdomen are less likely to have an organic basis than are those which remain in one place. Abdominal discomfort which is not made either worse or better by the taking of food or the emptying of the bowel is not likely to be arising in the digestive tract. Pelvic pain in a woman is not likely to be arising in disease of the pelvic organs if it is not made worse by menstruation.

Diarrhea which comes in short episodes is often due to panicky fear or to the eating of some food to which the patient is allergic. The woman who remains fat in spite of years of abdominal discomfort, if she hasn't gallstones, usually is suffering from a neurosis. The person with greatly exaggerated knee jerks is often suffering from a neurosis. The person who responds wrongly to barbiturates and opiates is usually somewhat psychopathic or is in a nervous breakdown. The patient who aches all over may be arthritic but usually is a bundle of nerves. The woman whose liver region is always sore, but who has never had colics, and has a gallbladder which functions well with the dye had better not be operated on. Occasionally her trouble is due to food allergy. Always it is well to remember that pseudocholecystitis and pseudo-ulcer are fairly common conditions. Chronic appendicitis is probably a rare disease and adhesions probably rarely produce symptoms.

Although a psychoneurotic, fussy and fretty woman can have a cancer or other serious disease, usually all her many aches and pains are arising in her disturbed brain and are being referred out to the periphery of her body. The point to remember is that pain is a common symptom of psychoneurosis. If this fact were more widely known, laboratory workers in this country would be spared an enormous amount of futile work and surgeons would be spared many disappointments because of a failure to cure.

SPONDYLITIC PAIN

A common type of pain which is often puzzling and is usually best recognized from the history arises in an arthritic spine. Such pain is easily recognizable when it consists of sharp stabs and comes in a person who is arthritic and has suffered from lumbago, sciatica, wry neck, cricks and sacroiliac lameness. The trouble is not so easy to diagnose when the distress comes in the epigastrium and several physicians have been hazarding diagnoses of angina pectoris, a poorly emptying gallbladder, peptic ulcer or gastritis. But even then one can often save the patient much expense for tests by eliciting such facts as that the distress is not really a pain but an ache or a burning and that it is felt superficially and not deep in. The fact that it has no relation to fast walking or going upstairs or getting angry indicates that it is not arising in the heart. The fact that the man can walk rapidly or go hunting or play tennis will show that his cardiac reserve is good. Under the

circumstances an electrocardiogram will probably not show anything wrong.

The facts that the distress has no relation to eating or belching or taking soda or passing feces or gas and that it was not helped by a Sippy regimen will indicate that it is not arising in an ulcer or any other disease of the digestive tract. The facts that it tends to get worse when the patient sits a while or lies down and that it goes away when he gets up and walks around a while make it almost certain that the disease is arthritic or fibrositic in nature.

CONSTITUTIONAL INADEQUACY

One of the most common problems in medicine is that of the woman who ever since girlhood has had one puzzling illness after another. She usually has had headaches, weak eyes, indigestion, constipation, abdominal pain, dysmenorrhea, palpitation, backache, bladder trouble, insomnia and aches and pains all over. She possibly has had several abdominal operations, none of which did her much good. Often one can see at a glance that she is constitutionally frail, and a few minutes of listening to her tale of woe will be enough to convince any experienced physician that no amount of examining will ever reveal one localized "cause" for all her troubles. Poor nervous heredity and "the contractor's having put in poor materials" are usually the best explanations for her miseries. Often tactful questioning will show that the woman has near relatives who have been insane or good-for-nothing, and to me this fact is the most important one in the whole history.

EXTREME FATIGUE

Another common problem is that of the woman who complains primarily of an extreme and distressing sense of fatigue for which several careful examinations have failed to reveal a cause. A few minutes questioning usually shows that she has had the distress for years, so it can hardly be due to tuberculosis or brucellosis or cancer. It is usually worse in the morning and clears away toward evening, so obviously it is not due to the strain of the day's work. Often the woman is not overworked, vacations have not helped, and in spite of all her years of misery she is well nourished and healthily looking.

In such cases the answer to just one question often gives all the explanation that I think is needed for the syndrome. This question is "Have any of your relatives suffered from mental disease, and particularly spells of depression?" If any have been so afflicted, the chances are that the woman's distress is her share of the family curse. Often also with an inherited psychopathic makeup the woman wears herself out with poor adjustments to living, with silly worrying and with much fretting against small discomforts.

A NERVOUS BREAKDOWN

It is a distressing fact that today, with all the wonderful diagnostic technics on which we physicians like to rely, one of the most common diseases that we see often fails to get recognized. I refer to the nervous breakdown of one kind or another. The difficulty is that the patient seldom thinks to mention the really important symptoms. Instead, he talks so much about pains and aches and what other physicians diagnosed and prescribed that even a consultant immediately thinks of disease in heart, digestive tract or glands or internal secretion and starts hunting for it with many tests. Unfortunately none of these tests can reveal the

fact that the man is almost out of his mind with nervousness or fatigue or fear of going insane. All that the tests do often is to turn up some unimportant abnormality which causes the physician to assume that the diagnosis has now been made and that no further thought need be given to it. Actually a very different diagnosis would have been made if the doctor had only thought to ask the man if he was working. Then it would have been learned that for months or years he hadn't worked because he couldn't meet people comfortably or stand having them around him. He was too nervous and restless and jittery to sleep or read or even to sit through a movie. Curiously, he who complained only of a little belching or abdominal discomfort did not mention the fact that for months he had been unable to talk business with any one for even a few minutes without getting prickly or faint or sweaty. He didn't confess that he couldn't make decisions that he couldn't talk to his wife without weeping or that he couldn't concentrate well enough or long enough to read even an editorial in the paper. Obviously the brain of such a man must be badly disorganized and sadly in need of rest.

A few more questions are then needed to help determine whether the nervous breakdown is due mainly to a bad nervous heredity, dissipation, unhappiness, overwork, heavy nervous strain, an insoluble life problem, cerebral arteriosclerosis, a slight stroke, some smoldering infection or a combination of several causes. In most of these cases it is of little use to go searching again and again for some focus of disease, because even if one was to be found it wouldn't be the cause of the breakdown and in most cases it would be unwise to do any operating until the man was rested and feeling more like himself.

SO-CALLED MUCOUS COLITIS

A considerable number of the women found in the offices of gastroenterologists have a disease which in most cases is easy enough to diagnose from the history alone. They have the irritable bowel syndrome. I do not like to call it spastic colitis because this term often breeds confusion and fear. Usually all the physician need do is to find out that for years the woman has had a sore, constipated and perhaps gassy colon which gets more painful and troublesome whenever she runs into worry or excitement or painful emotion. The woman may complain of attacks of diarrhea, but more careful questioning will show that what she means is that she has to go frequently and pass a little water and mucus and gas. Highly important will be the fact that the discomfort is felt in the lower half of the abdomen. This goes far to rule out disease in the stomach, duodenum or gallbladder.

THE IRRITABLE DIGESTIVE TRACT

Many persons who think they have an ulcer or some disease which could be cured with diet have only an overly irritable and reactive digestive tract. This fact can be ascertained easily by asking a few questions which will show that the distress complained of commonly follows within a few minutes after eating and more significant yet, within a few minutes after drinking cold water. Sometimes the patient will say that she bloats suddenly after drinking water or taking a cup of tea or some pop. In such cases the mere distention of the colon with an enema may cause much distress or the woman may fill with gas or get diarrhea whenever she becomes excited or frightened. Food may go

through her within an hour, and a small dose of laxative may act like a drastic purgative. Obviously, if the simple distention of the stomach or bowel by water can cause so much distress, there can be little hope of finding a diet that will be innocuous.

FOOD ALLERGY

Often the present day, long winded study of suspected allergic disturbances could be greatly shortened if only the patient was to be asked to go without any food for twenty-four or forty-eight hours. If this did not promptly relieve the indigestion, flatulence, constant headache, toxic feeling or stuffy nose complained of there could be little hope of finding any diet that would work well. Incidentally, the patient who says he couldn't bear to fast for twenty-four hours shows immediately that either he hasn't any guts or his pain cannot be very troublesome. If he promises to fast and then cheats, that also will tell the physician all he needs to know about him.

Usually one can tell the chronic dyspeptic from the allergic simply by asking a few questions. If a person is allergic and knows he must not touch egg white, he will usually say that he cannot eat cake or sherbet or anything containing egg, but the dyspeptic who says that he cannot touch eggs will often say that he can take one if it is boiled hard or beaten up in milk. Evidently, then it is the appearance of a poorly cooked egg which he does not like. He will say also that he cannot take anything raw or anything acid or anything fried or any pastry. Such generalizations do not mean anything to an allergist and suggest to him that the patient is a fussy, opinionated person who is full of prejudices.

MIGRAINE

Typical of the diseases that are best diagnosed from the history and the appearance of the patient is migraine. All one has to do is to recognize the story of a throbbing unilateral headache, followed by nausea and utter misery, or to see the miserable and apathetic patient in the attack. In typical cases this attack begins with a scintillating scotoma. Just to make it hard the woman will often have, in addition to the migraine, a milder nervous headache and sometimes a nuchal headache due perhaps to sore muscles. In cases of doubt it is helpful to find that near relatives have migraine that the woman had spells of "bilious vomiting" in childhood, that she was free from the spells during her pregnancies and that she slips into the headaches whenever she gets tense, worried, tired or unhappy, when she is about to menstruate or when she is going to give a dinner party.

For nearly a hundred years it has been known that this disease is an entity inherited from some ancestor. Its cause is in the brain, and the patients almost always have a peculiar temperament which contributes most to keeping up the trouble. They are nervous, hypersensitive, easily fatigued, worrisome and meticulous persons who take responsibility keenly and are inclined to work too fast and to do too much. Because I have never seen the tendency to the disease permanently eradicated by any abdominal operation I have little desire to make a lot of tests. I would much rather spend what time I can spare talking to the woman, finding out what her sources of strain are, showing her how she can live so as to cut down on the number of spells, and giving instructions as to how to go at relieving the headache the minute it appears.

A QUESTIONABLE BASAL METABOLIC RATE

Many a nervous, wide awake and energetic little woman goes to an internist to say that for a while her doctor treated her for myxedema because one estimate of basal metabolic rate was reported as -35 per cent. Significant then will be the fact that with the taking of thyroid substance she only became so much more jittery than she was before that she had to stop the medication. Fairly obviously she did not need it. The question then is: Shall the internist send her for more estimates of the basal rate or shall he spare his overworked laboratory girl? Usually he can spare her. Just let him talk to the woman for a few minutes and he will see that she can't be myxedematous, with her keen mind, mobile face, quick movements and active reflexes she just cannot have a rate of -35 per cent. The calculation must have been wrong.

Well, then, is she perhaps hyperthyroid? Probably not, if her skin is cool and her pulse normal, if she has no tremor, if she does not kick off the bedclothes and if she hasn't been losing weight. Under such circumstances many a wise clinician will not bother to send the patient for a measurement of the basal metabolic rate because he knows it almost certainly will be within the limits of normal. Incidentally, the limits of normal are wider than many physicians think. They are probably somewhere between -18 and $+18$ per cent. Many thin, frail women have a low basal rate of from -14 to -17 per cent, which is not due to hypothyroidism. Borderline measurements should always be repeated until at least two figures come out close together, and then no conclusion should be based on them which does not fit with the other facts obtained from the history and the physical examination. Any diagnosis based on one laboratory test the result of which does not fit with other facts of observation is usually wrong.

SUPPOSED DISEASE IN THE GLANDS OF INTERNAL SECRETION

Every so often a stout woman comes to an internist asking for treatment for some glandular disease which some one has told her she has. Already she has been treated extensively with hormones derived from the several glands of internal secretion, but she has not gotten better. The wise physician will note at a glance that she is normally feminine in build and appearance, her fat is evenly distributed, and she has no hair in places where it should not be. The fact that she has a normal menstrual cycle will indicate that the pituitary-ovarian mechanism must be functioning fairly well, and after running over in his mind the characteristics of the few known diseases due to a hypofunctioning or hyperfunctioning of the several glands of internal secretion the physician will see that she hasn't any of these syndromes. Then, perhaps, when he finds that obesity runs in her family, he will be satisfied to give her only a reduction diet.

SUPPOSED FEVER

A problem that often takes up much of the internist's time is that of supposed chronic fever. Usually the woman (it is significant that the patient is practically always a nervous woman) has already been subjected to many tests and much treatment for supposed brucellosis. Questioning usually shows that by fever the woman means 99.5°F on some afternoons. Often it can be noted, and this is highly significant, that on the first day in the office, when the patient was tense and anxious, the temperature, pulse, blood pressure and

leukocyte count were up a little, but later, when she calmed down, they all dropped to normal.

To one well acquainted with this syndrome, it will seem probable that, along with an unstable personality, the woman has unstable thermostats in her hypothalamus, and all she needs do is to stop worrying and to throw away her thermometer. Recent studies have shown that tense active persons normally have a temperature ranging around 99.3°F .

A helpful test in these cases is a measurement of the blood sedimentation rate. If this is under 15 mm in an hour, the woman is not likely to have any serious illness. Another helpful thing to do is to get a scout film of the abdomen, which usually shows that the spleen is normal in size. This tends to rule out brucellosis or other chronic infectious disease. Stereoscopic roentgenograms of the lungs should, of course, be made to help rule out tuberculosis.

THE OLDER MAN OR WOMAN WHO HAS SUDDENLY FAILED IN HEALTH

There is one type of case in which no good physician will want to trust only to a clinical hunch, and that is when a previously healthy person past middle age has just begun to fail and for the first time in his life has either become conscious of his stomach or gotten a pain, passed some blood or lost strength, weight or joy in life. Usually in such cases the cause is something serious, and always it must be searched for with care and pertinacity.

Unfortunately, one fairly common type of disease seen in these older persons who have begun to fail in health is seldom diagnosed correctly because the typical history is not elicited. I refer to intracranial arteriosclerosis with thrombosis of one or more small blood vessels in the brain. The disease should be easily recognizable when the illness comes suddenly at a certain minute of a certain day or when the patient wakes some morning feeling terribly dizzy and perhaps nauseated and confused. It is pathognomonic when, with this, there go changes in character, loss of memory or loss of joy in life and interest in loved ones and friends. Some of the patients lose considerably in weight, and a few become crippled with arthritis.

In those cases in which there was known to have been hypertension it is highly significant that after the dizzy spell the pressure fell decidedly, perhaps to normal, and remained there. This sign is probably pathognomonic. Sometimes the history of a little stroke cannot be obtained because the shutoff in circulation came slowly or at night, but then manifest character changes with loss of memory, a slowing up of the mental processes, an inability to work, loss of proper grooming or the coming of some signs of Parkinson's syndrome will make the diagnosis fairly easy and will show that the disease is in the brain and not in the thorax or abdomen.

RULING OUT CARCINOMA OF DIGESTIVE TRACT

In older persons with failing health it is often necessary to rule out cancer of the digestive tract and here again a few hints may be helpful. Since most cancers of the digestive tube ooze blood, a high hemoglobin reading is encouraging. Since most of these cancers become infected, normal leukocyte and polymorphonuclear cell counts are encouraging as is a low blood sedimentation rate. When six months of illness have passed and symptoms of obstruction have not appeared, this tends to rule out cancer of the small bowel and of

the left half of the colon. A normal liver function test is cheering, as it lessens the likelihood that metastasis has taken place.

A SUPPOSED GASTRIC HEMORRHAGE

Every so often the gastroenterologist sees a man who for months has been undergoing ineffectual treatment for ulcer. The diagnosis was based largely on the history that the man vomited blood or passed a tarry stool. But proper questioning soon shows that the little blood that was brought up was seen only after the patient had been retching for half an hour. This means that it came probably from a small ruptured vessel in the esophagus or stomach. If the stomach had been full of blood coming from an ulcer the story would have been very different. Then the minute he vomited perhaps a pint of bloody material would have come up.

More questioning is likely to throw great doubt on the nature of the black stool. Almost always the passage of tarry stools due to a real hemorrhage greatly weakens the patient. Often he faints on the bathroom floor, he is unable to walk up stairs, and usually he has to take to his bed and stay there for a week or two until some hemoglobin is regenerated and strength returns. Hence when one learns that the patient with a black stool went right on with his work and did not become weak or anemic one must doubt if he ever had a hemorrhage. If more questioning shows that at the time the dark stool was passed he was taking iron or some white powders, probably containing bismuth, it will be even more doubtful if he had any bleeding.

Because the man with an ulcer usually loses his pain for a while after a hemorrhage it is often helpful to ask about this, and if an abdominal discomfort went on unchanged after the passage of a black stool it probably was not due to an ulcer. Another strong indication that a man never had an ulcer is the story, commonly obtained, that a Sippy regimen, well carried out, failed to give any relief. When a man has a tractable ulcer without any complication such as penetration into the head of the pancreas or pyloric obstruction, he ought to get relief as soon as he is put to bed and given frequent feedings.

SUPPOSED PYLORIC OR DUODENAL OBSTRUCTION

A woman may say that she vomits violently in spells, and her physician suspects that she has an ulcer obstructing the pylorus. Or because on one occasion a roentgenologist saw stasis in her duodenum, it is feared that she will have to have a duodenojejunostomy. When, however, questioning shows that the woman never vomits food but brings up only a watery fluid, it will be obvious that her pylorus is open and food is not stagnating in the stomach. When further questioning shows that her spells always start with a unilateral headache it will become apparent that what she has been having are attacks of migraine.

Many a woman who complains of "vomiting" is really regurgitating food the minute she finishes eating, or even before. She has no nausea and does not retch. This trouble is always functional in nature and due to a hereditary predisposition plus nervousness or fatigue or a psychoneurosis. I have never seen it helped by any operation.

ARTHRITIS AND FIBROSITIS

One of the common problems the physician has to deal with every day is that of arthritis and fibrositis. Usually the question uppermost in the mind of the patient is whether he is going to be crippled. If he can be assured that he is not headed straight for a wheel-

chair he will usually go away happy and willing to put up with his pain and soreness. Often the physician can encourage the man by reminding him that he has been having attacks of stiffness in his joints off and on for most of his life without getting either deformed or crippled. Under these circumstances he will probably recover again.

With arthritic patients one of the most helpful tests is the measurement of the blood sedimentation rate because, if this is less than 10 mm in an hour, the chances are that the man has fibrositis rather than arthritis, which means that he is never likely to be crippled. Usually sinuses, tonsils and devitalized teeth have been attended to long before the consultant sees the patient and hence about the only place left in which he can hope to find infection is the prostate gland. In older patients with senescent changes in the joints one cannot expect to work much of a miracle by the removal of foci of infection.

THE PATIENT WHO CONTINUES TO HAVE TROUBLE AFTER AN OPERATION FOR ULCER

Often when a patient returns with abdominal pain after gastroenterostomy or subtotal gastrectomy the question is "Has the old ulcer flared up or has a new ulcer formed in the jejunum just below the stoma?" Often the best way of deciding this is to find out if the pain has shifted. If it is in the old place in the epigastrium the chances are that the old ulcer has become active again, but if the pain has moved down to a point a little below and to the left of the navel the chances are that a jejunal ulcer has formed. If the man has recently had a hemorrhage and had never had one before the operation, the chances are large that he has a new ulcer, this time in the jejunum.

THE PATIENT WHO STILL HAS PAIN AND INDIGESTION AFTER CHOLECYSTECTOMY

The first thing to do when a person comes complaining of abdominal distress after cholecystectomy is to find out whether before operation there were any colics or other symptoms strongly indicating the presence of gallbladder disease or whether the operation was done largely because some roentgenologist thought the gallbladder was slightly abnormal. If the symptoms originally were those of a psychoneurosis and the operation did no good, the chances are that it was ill advised, and in attempting to make a diagnosis the physician can leave out of consideration residual disease in the bile ducts. It is helpful to find out whether the gallbladder contained stones. If it did and if the patient is now complaining of attacks of pain, perhaps with chills and fever and slight but definite jaundice, the chances are that a stone was left in the common bile duct. But if at operation there were no stones in the gallbladder there is little likelihood that now there is one in the duct. Whenever the patient says that he has had jaundice he should be cross examined because often it turns out that all he had was a questionable sallowness.

COMMENT

It is suggested that for the duration of overworked physicians spare overworked roentgenologists and laboratory technicians and make more of their diagnoses quickly with the help of a few shrewd questions. A number of hints have been given for the making of such quick diagnoses. Today many diagnoses could be made with greater accuracy if based on a good history rather than on tests, in many conditions the diagnosis can be made from the history alone.

ERYSIPELOTHRIX RHUSIOPATHIAE SEPTICEMIA DIAGNOSIS AND TREATMENT

REPORT OF FAIAL CASE OF ERYSIPELOID

JOSEPH V KLAUDER, MD

Dermatologist, Outpatient Department, Philadelphia General Hospital

WITH THE TECHNICAL ASSISTANCE OF CIARA KAST
AND LORAINI GROSZIN

PHILADELPHIA

The cutaneous disease that Rosenbach in 1884 designated erysipeloid is now known to be an infection caused by *Erysipelothrix rhusiopathiae*, the organism of swine erysipelas. Erysipeloid occurring at the site of injury, usually the hand, in abattoir workers, fish handlers and retail butchers, is a common occupational disease. Erysipeloid resulting in blood stream infection and death is rare.

The case reported here concerns a butcher who cut his finger while working. Although we did not see him at that time, evidence suggests that a severe form of erysipeloid resulted from this injury. Blood stream infection with *Erysipelothrix rhusiopathiae* ensued, from which he died six months after the injury. The organism was recovered from antemortem blood culture. Symptoms of the septicemic form of the infection in man are not described in medical textbooks. The clinical picture is somewhat comparable to the infection in swine, which is well known to veterinarians.

REPORT OF CASE

Clinical History—J Z, a white man aged 46, a retail butcher, came under our observation when he was admitted to the medical service of Dr David W Kramer at the Philadelphia General Hospital on Sept 18, 1941.

On April 15, 1941 the left thumb was lacerated by a meat bone. No particular attention was paid to the injury until three days later, when the thumb began to swell, compelling him to stop work on April 21. The physician who treated him reported extensive infection of the thumb, periostitis of both bones and cellulitis of the soft tissues. The site of infection was incised and drained, but with little improvement. A roentgenogram of the thumb on May 7 disclosed necrosis of the base of the distal phalanx. Another physician advised amputation, which was not performed. He reported an infectious arthritis of the interphalangeal joint with erosion of the distal phalanx. On May 16 it was reported that the thumb was considerably swollen. There was an open area, the remains of previous incision, with serous discharge but no pus. The surrounding tissues were not inflamed and there was no evidence of extension of infection. The patient's general condition was good, there were no systemic symptoms. The thumb gradually improved, complete healing ensued, enabling him to return to work on June 9. He worked regularly until August 15, when he stopped work because he felt weak and sick. He continued to feel weak and spent most of the time in bed. A physician who visited him reported that he was anemic and had fever and a purpuric eruption and advised admission to the hospital.

Physical Examination—The patient was well developed and well nourished. He appeared ill and anemic. The skin was yellowish white. Scattered over the extremities and trunk there were a number of purpuric macules varying in size from

0.5 to 4 mm, the color varied from shades of red to purple. There was a scar on the left thumb but no evidence of infection. The tongue and mucous membranes were pale. The heart was not enlarged to percussion. The heart sounds were soft and distant with normal rhythm. There was a blowing systolic murmur heard at the apex. The liver was enlarged two fingerbreadths below the costal margin. The edge of the spleen was palpable.

The blood pressure was 150 mm of mercury systolic and 70 mm diastolic, the pulse rate 90, the temperature 100 F and the respiratory rate 25.

Laboratory Examination—Repeated examinations of the urine revealed 2 to 1 plus albumin, occasional casts and white blood cells and on one occasion red blood cells. The Fishberg test revealed fixation of the specific gravity at 1.010 to 1.011. On admission the erythrocyte count was 2,000,000 and the hemoglobin content 49 per cent (7.15 Gm). The erythrocyte level decreased to 1,560,000 on September 25 and to 1,000,000 on October 2. The white blood cells numbered 8,800. The differential count was 74 per cent neutrophils, 16 per cent lymphocytes and 10 per cent monocytes. The sugar content of the blood was 87 mg per hundred cubic centimeters and the total cholesterol content was 136 mg with 26 mg (19 per cent) of cholesterol esters. Blood Wassermann and Kahn tests gave negative results. Agglutination tests for typhoid, paratyphoid, *Brucella abortus* and *Pasteurella tularensis*, and the Weil-Felix

Fig 1—Purpuric spots and purplish disciform lesions. The eruption resembled erythema multiforme more than any other skin disease (see figure 6 for comparison).

reaction revealed negative results. The blood urea nitrogen gradually rose from 50 mg per hundred cubic centimeters on admission to 90 mg on October 13. Of four blood cultures three showed a small, slender, gram positive bacillus.

Course of Illness—The pulse remained elevated and the temperature spiked between 99 and 102 F. The heart became enlarged and a short diastolic apical murmur was heard when the patient was in the left lateral position. The standard urea clearance test diminished to 8 per cent. The purpuric like macules on the trunk faded, followed by a new outbreak of purplish macules, with smooth, nonelevated surfaces, on the dorsa of the hands and on the forearms. Here the lesions were disciform, varying in diameter up to about 5 cm (fig 1). Some became confluent, others were somewhat rounded with irregular borders. Around the elbows and ankles the eruption consisted of discrete spots. There were purpuric-like linear lesions that followed some creases on the palms and palmar surfaces of the fingers (fig 2), concomitant with these palmar lesions there were swelling, tenderness and pain of the carpal and metacarpal joints of both hands. The patient also complained of pain in other joints. Transfusions and sulfathiazole (the blood concentration was 12 mg per hundred cubic centimeters) were without effect. The patient became progressively weaker and died on October 17.

Clinical Diagnosis—This was subacute bacterial endocarditis. In the terminal stage of the disease, *Erysipelothrix rhusiopathiae* septicemia was suggested. The organism recovered from blood culture was identified as *Erysipelothrix rhusiopathiae* after death.

Necropsy—This was performed twenty hours after death. The body was well developed but poorly nourished and showed neither icterus nor peripheral edema. The previously described cutaneous changes were not obscured by livor mortis. The pleural, pericardial and peritoneal surfaces were apparently normal. The lungs, aorta, gastrointestinal tract, pancreas

Fig 2—Purplish linear lesions in some creases of the palm and palmar surfaces of the fingers

extrahepatic biliary passages, lower urinary tract, genitalia and adrenals were not remarkable on gross examination.

The heart showed moderate hypertrophy of the left ventricular myocardium and a moderate degree of dilatation of each ventricle. Adherent to one aortic leaflet there was a pinkish yellow friable vegetation¹ (1/4 inch in diameter). The other valves and the coronary arteries were not remarkable.

The spleen was four times the normal size and presented a moderately firm recent infarct which took the form of a transverse band 1 inch wide.

The liver was somewhat enlarged and cut with decreased resistance. The inferior edge was rounded. On the cut surface

Fig 3—Section of endocardial vegetation showing large amorphous masses in the center, pus cells and fibrin. Hematoxylin and eosin stain. Reduced from a photomicrograph with a magnification of 63 diameters.

the normal hepatic architecture was obscured by a diffuse, irregular pale pink and yellow mottling.

The kidneys were large and swollen. On both the subcapsular and cut surfaces there were scattered petechiae.

1. Since death resulted from accidental injury, necropsy was performed by the coroner's physician. No culture was made of the endocardial vegetations.

Anatomic Diagnosis—This was acute bacterial endocarditis (aortic valve), cardiac hypertrophy and dilatation, recent infarct of the spleen, acute hepatitis with fatty change and acute focal glomerulonephritis.

Microscopic Observations—Heart: A section through the involved aortic cusp, stained with hematoxylin and eosin, showed the leaflet definitely thickened by layers of fibrin in various stages of organization. The endothelium was disrupted at the site of attachment of a vegetation. The latter was composed in some parts of closely packed polymorphonuclear leukocytes with a few large mononuclear cells; in other areas there were fine and coarse wavy threads of fibrin, small foci of degenerated erythrocytes and an occasional pus cell. Scattered through the vegetation especially in its periphery, were numerous doughnut shaped amorphous gray masses with strongly eosinophilic margins (fig 3). After staining with the Weigert modification of the Gram stain, these masses and the tissue surrounding them showed many gram positive rods and threads scattered singly, in clumps and in linear formation (fig 4).

Spleen: Two thirds of the section showed extensive areas of necrosis. The viable splenic tissue, the pulp, showed occasional histiocytes filled with blood pigment and a few giant cells, probably megakaryocytes.

Liver: Most of the liver cells were distended by large globules of fat. In numerous foci well defined acute inflammatory infiltrations occurred in and around the periportal connective tissue.

Fig 4—Section of endocardial vegetation showing *Erysipelothrix rhusiopathiae*. Slight nodular irregularities of some filaments suggested beading. Gram Weigert stain. Reduced from a photomicrograph with a magnification of 598 diameters.

Kidney: Many glomeruli were unusually cellular, several were the seat of recent thrombosis with a moderately severe localized leukocytic infiltration surrounding many of the necrotic foci. Occasionally there was a localized proliferation of the capsular epithelium with the formation of an epithelial crescent. Few of the tubules contained erythrocytes.

Microscopic Diagnosis—Aortic Valve: Acute bacterial endocarditis with bacterial colonization.

Spleen: Recent septic infarction.

Liver: Focal acute hepatitis, fatty metamorphosis.

Kidney: Focal acute embolic glomerulonephritis.

BACTERIOLOGY

The organism obtained from an antemortem blood culture was identical morphologically, culturally and serologically with a known strain of *Erysipelothrix rhusiopathiae*.²

Morphology—The organism was a slender, straight or slightly curved rod from 1 to 15 microns long, arranged singly or in small groups or in chains. It was nonmotile, non-spore.

²—This strain in the laboratory of the Research Institute for Cutaneous Medicine was obtained from a lesion of diamond skin disease in 1941. The original culture has since been maintained in its true form. Morphology and virulence of the organism have remained unchanged. This method is a convenient one for maintaining a virulent stock strain of *Erysipelothrix rhusiopathiae*.

forming and was gram positive. In old broth cultures the organism grew in longer forms.

Cultural Characteristics—The organism grew well on blood agar. Scanty growth was obtained on heart infusion broth (Bacto) but grew well in this medium (turbidity in twenty-four hours) with the addition of ascitic fluid (10 per cent). Better growth was obtained on a modified heart infusion broth (Burky and Henton³). Liquefaction of gelatin did not occur. Voges-Proskauer and methyl reactions were negative. Indole and hydrogen sulfide were not produced.

Virulence—White mice inoculated intraperitoneally with 0.1 cc of a 1:10 dilution of a forty-eight hour culture on Burky's medium were moribund in two to three days. The organism was recovered in pure culture from the heart blood.

Serum Reactions—The organism was strongly agglutinated by a concentrated antiserum. Dr. W. F. Verway of Sharpe & Dohme also performed agglutination tests with positive results with some serums; agglutination resulted in dilutions reaching 1:1,600. Two rabbits that had been previously inoculated intravenously with 2 cc of a forty-eight hour broth culture were immunized as follows: Injections of 0.5, 1, 2 and 4 cc of forty-hour living broth cultures of organisms from our patient were given intravenously at four day intervals. Serum from these animals agglutinated a known strain of *Erysipelothrix rhusiopathiae* in dilutions reaching 1:2,560. The same antigen was not agglutinated by normal rabbit serum used as a control.

Biochemical Characteristics

	Our Organism	Known Strain of <i>Erysipelothrix rhusiopathiae</i>	Russell and Lamb ⁴	Bergey ⁵
Dextrose	Acid*	Acid	Acid	Acid
Maltose				
Sucrose				
Lactose	Acid	Acid	Acid (litmus milk)	Acid
Mannitol				Acid (late)
Xylose	Acid	Acid		

* Acid, but no gas.

Biochemical Reactions—The accompanying table shows results of fermentation reactions with a known strain and with an organism from our patient. For comparison, fermentation reactions given by Russell and Lamb⁴ and by Bergey⁵ are shown. It will be seen from the table that fermentation reactions with the known strain and with the organism from our patient were identical. Compared with the results of Russell and Lamb⁴ and of Bergey⁵ there was a discrepancy in reaction with mannitol and xylose. It is to be noted, however, that fermentation reactions, as reported by different investigators working with different strains, have varied. Some report a variable reaction with xylose and others an acid reaction with xylose and with mannitol.⁶

In addition to our study the organism was identified as *Erysipelothrix rhusiopathiae* by the Pathological Division of the Bureau of Animal Industry of the United States Department of Agriculture in Washington, D. C. Dr. H. W. Schoening of this division reported: "Both cultural examination and mouse and pigeon inoculations proved the organism to be typical of *Erysipelothrix rhusiopathiae*."

THE ORGANISM

Bergey⁵ classified *Erysipelothrix rhusiopathiae* among the "higher bacteria" of the order of Actinomycetales. There are three generally accepted strains, human,

swine and mouse, although the organism has been found in a considerable assortment of animal species either as a harmless parasite or as a pathogen. Its wide dissemination is extraordinary. It is found wherever nitrogenous substances are decomposing. In putrid material the organism is capable of retaining its viability and virulence for months. In certain environments it exists in the soil as a saprophyte. The organism has been recovered from the slime of fish,⁷ from houseflies⁸ and from putrefying horseflesh.⁸ The organism is not the cause of any known disease of fish. It appears that the slime of fish attracts the organism from refuse thrown in the water and other decaying matter and that change of environment increases the virulence.⁹

The virulence varies considerably in different species and in the same species. The organism has a capacity to change suddenly from a harmless saprophytic to a pathogenic parasite. This transition occurs particularly in swine. Man is relatively immune, particularly when the organism enters through the gastrointestinal tract. Pigeons and white mice are highly susceptible to artificial infection, rabbits and guinea pigs, considerably less.

THE INFECTION IN SWINE

The infection is one of the most serious diseases of swine. It is manifested in three forms. A mild form ("diamond skin" disease) is characterized by slight constitutional symptoms and the presence of quadrangular, rectangular and disciform lesions, bright red spots and ill defined blotches. The lesions, becoming confluent, form bizarre designs constituting an eruption pattern peculiar to this disease. This form is the more frequent in the United States. Frequently the cutaneous lesions are not visible until after the animal has been slaughtered, scalded and cleaned. A severe, frequently fatal, form is characterized by constitutional symptoms of septicemia, the presence of diffuse areas of erythema and at times vesicles, petechia and necrosis. A chronic form is characterized particularly by polyarthritis and at times symptoms referable to a vegetative type of endocarditis. Endocarditis, when occurring, usually involves the mitral valves, and the vegetations tend to attack and invade the endocardium.¹⁰

THE INFECTION IN MAN

The most common form of the infection in man is erysipeloid. Other forms are less well known and somewhat correlate manifestations of the disease in swine. Erysipeloid is a mild, rather localized cutaneous infection occurring usually at the site of injury, invariably the hand (fig. 5). Infection frequently arises from occupation (88 of 100 cases reported by one of us¹¹) in persons handling fish, the products of swine, dead matter of plant and animal origin and other sources. Pain, intense swelling, purplish red erythema at the site of inoculation and absence of suppuration are distinctive features. The disease may be wrongly diagnosed as pyogenic infection.

Arthritic symptoms particularly of the hand may accompany erysiploid and may persist after disappearance of the cutaneous lesions. In this event joints other than the hand may become affected.¹²

Generalized infection with polyarthritis and constitutional symptoms (with negative blood culture) has been reported.¹³

A few cases of septicemia with endocarditis have been reported. Russell and Lamb's¹ case however is the first one in which endocarditis was proved at necropsy with recovery of the organism from the heart blood and endocardial vegetation. They appropriately write that the apparent rarity of the disease as suggested by the literature with only 3 questionably identified cases is probably not entirely justified. While endocarditis in swine is an infrequent complication of swine erysipelas, it is observed and generally recognized by veterinarians. For this reason the opinion is ventured that more cases in man will be recognized in the future as the prevalence of erysiploid infection is rapidly being publicized in the medical literature.¹

The report of Russell and Lamb¹ concerned a lobster fisherman who presented a hospital course of sepsis and endocarditis. No port of entry of infection could be demonstrated and there were no cutaneous lesions. Death occurred after three months of illness. Antemortem blood culture revealed *Erysipelothrix rhusiopathiae*. Vegetative endocarditis of the aortic and mitral valves was found at necropsy.

In the case reported by Fiessinger and Brouet¹⁴ infection occurred from eating salt pork. The initial symptoms were malaise, anorexia (diarrhea was absent) and an eruption. The latter was described as red spots on the trunk and extremities becoming confluent in places, forming large plaques. The fever ranged from 37.6 C to 39 C (99.7 F to 102.2 F) and there was a painful swelling of one knee. The ears were swollen, purplish red¹⁵ and painful resembling a traumatic hematoma and purpuric spots appeared on the face. There was severe anemia, leukopenia with the monocytes reaching 22 per cent. Blood culture revealed *Erysipelothrix rhusiopathiae*. The patient rapidly improved after administration of immune serum. Soon after discharge from the hospital acute nephritis and cardiac failure ensued with fatal outcome.

Prausnitz's¹⁶ patient was a 10 year old child. There were bluish red spots on different parts of the body, joint pains and a clinical picture of sepsis with endocarditis. Blood culture disclosed *Erysipelothrix rhusiopathiae*. Death resulted after six months of illness. Necropsy was not performed.

The 2 cases reported by Gunther¹⁷ to which Russell and Lamb refer as questionably identified cases of septicemia with endocarditis occurred in veterinarians accidentally inoculated with culture of the organism. Bacteriologic studies were lacking however in both cases.

COMMENT

The infection of the thumb apparently was a severe form of erysiploid. When we first saw the patient only a scar remained. It was reported that there was periostitis and necrosis of the bone. Reexamination of the roentgenogram showed unmistakable evidence of necrosis of the bone. This complication of erysiploid is not recorded as occurring in the medical literature. Despite this it is reasonable to ascribe necrosis of bone to the organism causing blood stream infection. Periostitis and osteitis, however occur in the infection in swine.¹⁸ Nonsuppuration at the site of injury is against pyogenic origin of bone involvement in our case. The injury to the thumb and the patient's occupation were the only evidences of the port of entry of *Erysipelothrix rhusiopathiae* infection.

Failure to demonstrate the organism in culture taken from the endocardial vegetations is compensated by its demonstration in stained sections from such vegetations (fig. 4). The organism seen as filaments in the section had slight nodular irregularities suggesting beading. In

Fig. 5.—Erysipeloid of eight days duration in an abattoir worker who cut his thumb while working. This is the most common form of infection with *Erysipelothrix rhusiopathiae* in man. Pain, tense swelling, purplish red erythema and absence of suppuration are distinctive features.

old cultures especially on broth beading of the filamentous forms of the organism occurs.

The course and symptoms of the infection were similar in many respects to those in the case reported by Fiessinger and Brouet.¹⁴

DIAGNOSIS AND TREATMENT OF ERYSPELOTHRIX RHUSIOPATHIC SEPTICEMIA

There are three cardinal symptoms of the infection in swine—an eruption, symptoms referable to the joints, and endocarditis. This triad although occurring in man is not diagnostic. Moreover diagnosis before endocarditis develops is desirable. The eruption and monocytosis probably have more diagnostic value since other symptoms of the infection in man are common to any septicemia. Diagnosis is facilitated through the following considerations:

Anamnesis.—The history of erysiploid or of local cutaneous infection occurring in the course of an occupation or from a source entailing exposure to the organism. Illness after eating partly cooked pork or its product, fish or tainted food.

18 Van Es, L. and McGrath, C. B. Swine Erysipeloid. Bull. U. S. Bureau of Animal Industry 34: 1-12 1912.

Eruption—Purplish red, hematoma-like swelling of the ears with necrosis (Fressinger and Brouet's paticnt) is a distinct symptom if frozen ears are excluded. The reported occurrence of "purpuric spots," "bluish red" lesions and "red spots" have limited diagnostic value. The formation of disciform lesions (fig 1) and large plaques lacking characteristic features of erythema multiforme is of more diagnostic value (fig 6). Purplish linear lesions in creases of the palms and palmar surfaces of the fingers are unique cutaneous lesions (fig 2). The character of the rash and its distribution in our patient resembled the purpuric and petechial eruption that characterizes the extrameningeal types of acute and chronic meningococcal infection.¹⁹

Monocytosis and *Listerella Monocytogenes* Infection in Man—In the few reported cases of septicemia in man there was an increase in the monocytes. Such increase is of diagnostic significance, since few diseases cause monocytosis in man, and is consistent with the following observations. In Barber's²⁰ study it was noted that among features common to both *Listerella monocytogenes* and *Erysipelothrix rhusiopathiae* was the production of monocytosis in rabbits. In some rabbits the increase in monocytes reached 30 per cent

Fig 6—Erythema multiforme for comparison, showing bluish red, disciform lesions with central clearing (target shape) and with concentric rings (erythema iris). The central clearing and concentric rings, characteristic features of erythema multiforme, were lacking in the eruption of our patient.

Seastone²¹ observed that inoculation of chickens, rabbits and guinea pigs caused monocytosis. Egehoj²² noted monocytosis in *Erysipelothrix rhusiopathiae* infection in swine.

Listerella monocytogenes and *Erysipelothrix rhusiopathiae* are similar morphologically and culturally. One difference, however, is that *Listerella* is motile whereas *Erysipelothrix rhusiopathiae* is nonmotile. Both organisms are the cause of widespread infection in animals. The common result of *Listerella* infection in cattle²³ and sheep²⁴ is encephalomyelitis. "In rabbits, guinea pigs, chickens, septicemia is observed. In rodents, a monocytosis is considered pathognomonic. A similar monocytosis occurs in chickens but has not

been observed in ruminants."²⁵ In man,²⁶ *Listerella* causes meningoencephalitis, and the organism has been recovered from the blood of patients with infectious mononucleosis.²⁷

In view of the difference in the clinical picture of systemic infection with *Listerella* and with *Erysipelothrix* in man, there is less likelihood of confusing the two infections despite the presence of monocytosis and a preliminary blood culture report of a gram positive slender rod.

Agglutination Test—This has not been studied in septicemia in man. Grey, Osteen and Schoening²⁸ studied the value of the agglutination test in the diagnosis of the infection in swine. In the acute stage they observed that, although the test may be positive, this was quite variable. More uniform results were obtained in animals with joint lesions visible on clinical examination. Karlson and McNutt²⁹ observed that microscopic agglutination tests conducted on swine dead or dying of the septicemic form of the disease gave negative results.

In erysipeloid, Bierbaum and Gottion³⁰ observed that agglutination did not exceed dilutions of serum ranging from 1:20 to 1:40, in which dilutions the serums of normal persons caused agglutination.

Intracutaneous Test—Biberstein,³¹ notably, studied the diagnostic value of an intracutaneous test in erysipeloid and in experimentally produced infection in laboratory animals. His studies were conducted with an antigen comprising "fresh" vaccine and "fresh" filtrate made from a twenty-four hour bouillon culture of *Erysipelothrix rhusiopathiae* and "old" vaccine and "old" filtrate made from a ten day old bouillon culture. Best results were obtained with "old" filtrate, which gave positive results in 88 per cent of 17 persons with active erysipeloid and in 50 per cent of 6 persons who had recovered from erysipeloid. With the same filtrate, 5 per cent of 60 normal persons gave a positive reaction.

Recovery of Organism—In addition to blood culture, it is to be expected that the organism can be recovered by culturing an excised piece of affected skin. By this method it has been demonstrated in "diamond skin" disease and in erysipeloid and was demonstrated also in Klauder's¹¹ patient who had generalized cutaneous lesions as long as fifteen months after onset of the infection.

Erysipelothrix rhusiopathiae septicemia should be considered when the clinical diagnosis is subacute bacterial endocarditis with a blood culture report of a gram

19 Mitchell Heggis G. B. Skin Manifestations of Meningococcal Infection, Brit J Dermat & Syph 54: 283-307 (Nov.) 1942. Comparable to demonstration of meningococcus in smear obtained by friction over the petechiae or purpuric lesions and in microscopic section of such lesions, it would be interesting to know whether *Erysipelothrix rhusiopathiae* could be similarly demonstrated.

positive rod provided the organism is nonmotile and non-spore forming. Other descriptive names that may be given the organism before identification are gram positive rodlike bacilli, coccoid or streptobacilli. In such event, in order to avoid delay, administration of immune serum should be considered before identification of the organism is established.

Treatment—Immune serum should be employed in massive doses in a short space of time.³¹ The following treatment is suggested: 100 cc intravenously every twelve hours for the first four to six injections, further treatment depending on the clinical results.

It is to be noted that sulfathiazole in our case and sulfanilamide in Russell and Lamb's case were ineffective. In a study³² by one of us it was observed that the sulfonamide compounds were ineffective in the treatment of experimentally produced infection in mice (survival of 12–5 per cent) and also ineffective when combined with subcurative doses of immune serum.

Clinical Notes, Suggestions and New Instruments

ERYTHROBLASTOSIS FETALIS (HEMOLYTIC DISEASE OF THE NEWBORN) OCCURRING IN ONE OF TWINS

DOUGLAS H. KARIHER, M.D., ROCHESTER, N. Y.

There has recently been called to my attention a case of erythroblastosis fetalus which occurred in 1 infant of twins while the other twin is perfectly normal. In view of the recent interest in the blood factor Rh as the etiologic agent of erythroblastosis I feel that this case is of sufficient importance to warrant publication. Complete blood Rh studies have been carried out in this case and they add further support to the thesis that erythroblastosis is the result of isosensitization of an Rh negative mother by an Rh positive fetus. Considerable evidence¹ has been brought forth to prove the truth of this statement.

In a recent publication² it was suggested that the term 'hemolytic disease of the newborn' be used rather than 'erythroblastosis fetalus,' since the erythroblastosis seen in the infant is merely one of the results of the underlying cause which is hemolysis of the fetal red blood cells. Furthermore, erythroblastosis may not be a prominent feature of the disease in certain cases whereas hemolysis is always present. Henceforth therefore in this discussion I shall use the term hemolytic disease of the newborn instead of erythroblastosis fetalus.

REPORT OF CASE

Mrs. A. DeH., a woman aged 41, secundipara, tertigravida, had given birth to living normal infants as the result of her first two pregnancies which were full term. The third preg-

nancy terminated in 1941 by abortion at 2½ months. The most recent pregnancy, the fourth, was a twin pregnancy complicated by hydramnios. The expected date of confinement was April 3, 1943. On March 11 labor was induced by her attending physician at another hospital by rupturing the membranes of one of the twins. After an uneventful labor the patient delivered twin male infants, the first, baby A, weighing 5 pounds 13 ounces (2,635 Gm.) and the second, baby B, weighing 6 pounds

TABLE 1—Results of Determinations

	Group	Rh	Anti Rh
Father	A	+	
Mother	A	0	+
Normal twin	A	0	
Twin with hemorrhagic disease of the newborn	A	+	0

The blood Rh determinations on the family showed the mother and the normal twin to be Rh negative and the twin with hemorrhagic disease of the newborn and the father to be Rh positive.

7 ounces (2,925 Gm.). The placentas were typical of a double ovum gestation there being two separate placentas and sets of membranes. Baby B looked perfectly normal at birth and continues to be a healthy infant. Baby A, on the other hand, was quite pale, cried weakly and had a dusky icteric tint to the skin. Within twenty-four hours after birth the infant was definitely icteric and looked poorly. When the infant was 34 hours old it was given a transfusion with 50 cc of the father's blood. Four hours later just as a second transfusion was being prepared, the infant died.

A blood count on this baby at the time of birth showed a red blood cell count of 2.9 million and a hemoglobin value of 62 per cent. A blood smear showed 28 per cent erythroblasts of all varieties. I was given blood on the mother and father as well as the twin babies for Rh determination. The findings are shown in table 1.

Autopsy on baby A showed findings typical of hemolytic disease of the newborn. In addition to the icterus there was slight edema present in the subcutaneous tissues. The liver weighed 175 Gm., with 78 Gm. being the normal weight. The spleen was also somewhat enlarged. Sections of these organs showed an unusually large number of active hemopoietic centers. Hemopoiesis was also noted in the adrenals. Unfortunately the placentas were not saved for study.

COMMENT

This case seems to present clearcut evidence that the Rh factor is the etiologic agent in hemolytic disease of the newborn. From table 1 we note that the father is Rh positive and the mother is Rh negative. One of the double ovum twins is Rh negative and is therefore normal. The other twin is Rh positive and died of hemolytic disease of the newborn. It would seem uncontroversial that the Rh factor from the diseased twin crossed the placenta thus gaining access to the maternal circulation and there stimulating the production of anti-Rh isoantibody, which in turn crossed the placenta into the fetal circulation and there destroyed the fetal red blood cells. Evidence to support his statement can be gained from the fact that the anti-Rh isoantibody was found in the maternal circulation (table 1). This is demonstrated by the agglutination of the cells of the affected infant when these cells are set up in an agglutination test with the maternal serum.

It has been stated that the Rh antigen crosses the placental barrier from the fetus to the mother and there stimulates antibody production. Just how this process takes place is still a matter for speculation. It has been stated that defects in the placenta allow the fetal red cells carrying the Rh factor to enter the maternal circulation and Javert³ has reported finding such defects in placentas from cases of hemolytic disease of the newborn. A more plausible mechanism would seem to be the passage across the placenta of the breakdown

32 Erysipelothrix rhusiopathiae antiserum can be obtained from Sharpe & Dohme, Inc., Philadelphia; Pittman Moore Company, Indianapolis; Lederle's Laboratories, Inc., Pearl River, N. Y.; Jensen Salsberry Laboratories, Kansas City, Mo.; and other manufacturers of biologic products in veterinary medicine.

33 To be published.

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry.

Dr. F. S. Fumia, the attending physician, allowed the author to study this case. Dr. Frederick Summerill, pathologist and director of laboratories at Highland Hospital, Rochester, N. Y., helped in obtaining detailed information.

products of physiologic fetal red blood cell destruction. The Rh factor then may be in a molecule small enough to get through the placental barrier.

It will be recalled from the case history that the diseased infant was only slightly icteric at birth but within twenty-four hours of birth became definitely so. This is not an infrequent observation, and it would seem to be somewhat contradictory to our views of isosensitization of the mother being the particular factor in the disease. On the contrary it lends support to this idea. We tend to think that the fetal red cells hemolysis stops abruptly the minute the infant is delivered. However, this is probably not the case, since the infant still carries antibody, which it obtained from the mother for a short time after birth. This antibody will continue to react on the infant's red cells, just as it did when the infant was in utero. However, now there is no means for the elimination of the end products of red cell destruction and they accumulate in the infant's body, whereas, while the fetus was in utero, these end products were probably eliminated from the fetus by means of the interchange of substances in the placenta.

TABLE 2—Results of Mating (After Levine⁴)

Mother Rh— rh rh	Offspring	Father Rh+ Rh rh
	50% Rh rh Rh+	
	50% rh rh Rh—	

About 50 per cent of offspring from mating of Rh negative mother and heterozygous Rh positive father will be Rh+, and 50 per cent will be Rh—.

The answer as to how 1 fetus or twins could be Rh positive and the other Rh negative can be found in the work of Landsteiner and Wiener⁴ on the heredity of the Rh factor. In my case the mother is Rh negative and hence would have the genotype rh rh. The father is Rh positive and could have one of two genotypes, Rh Rh or Rh rh. If his genotype was Rh Rh, then all the offspring of this mating would be Rh positive, since all the progeny would carry the dominant gene Rh. However, we know that 1 of the twins is Rh negative, therefore the father's genotype must be Rh rh and would be termed heterozygous. Table 2 shows the results of mating an Rh negative mother and a heterozygous Rh positive father. We see that there is an equal chance of getting an Rh positive and an Rh negative infant in the progeny. In my case of double ovum twins, it merely happened that the two genetic types occurred in the same pregnancy instead of in succeeding pregnancies, as is the more common occurrence.

FATAL BULLOUS DERMATITIS FOLLOWING ADMINISTRATION OF SULFADIAZINE

MAJOR S. I. GREENBERG AND CAPTAIN A. L. MESSER
MEDICAL CORPS ARMY OF THE UNITED STATES

Sulfadiazine is probably the least toxic of the sulfonamide compounds in common use today and causes the lowest incidence of drug eruption. Ensworth and his associates¹ reported only 4 cases of drug rash in a series of 239 cases of pneumonia treated with sulfadiazine. In a series of 660 treated with sulfadiazine by Dowling and Lepper,² 10 instances of dermatitis occurred. These were scarlatiniform, morbilliform and urticarial, and all subsided on cessation of administration of the drug.

However, more serious dermatologic complications have been reported. Raffetto and Nichols³ reported a nearly fatal pemphigus-like rash occurring in a 10 year old girl following sulfadiazine therapy.

REPORT OF CASE

D. J., a white man aged 20, was admitted to the Station Hospital March 4, 1943 complaining of sore throat and cough. On physical examination a small area of consolidation was found in the base of the left lung posteriorly. X-ray examination confirmed the diagnosis of bronchopneumonia of the left lower lobe. Urinalysis was negative. The blood count revealed 4,750,000 red blood cells per cubic millimeter and 8,800 white blood cells per cubic millimeter with 78 per cent polymorphonuclear leukocytes.

Sulfadiazine was started on March 4 with 2 Gm. as an initial dose and 1 Gm. every four hours. This was discontinued on March 8. It was started again the same day when the patient's temperature rose to 102 F. Physical and x-ray examination revealed the spread of the pneumonia to the left upper lobe. On March 12 the physical and x-ray examinations revealed considerable resolution of the pneumonia, and sulfadiazine was discontinued. The blood sulfadiazine level was 98 mg. per hundred cubic centimeters on that day. The patient had received a total of 49 Gm. of sulfadiazine in the period of eight days. He appeared somewhat confused at times during the period in which he was receiving sulfadiazine. He vomited twice but retained fluids well. The patient had also received occasional doses of codeine sulfate 0.06 Gm. and capsules containing acetyl salicylic acid, acetophenetidin and caffeine.

On March 13, the day after administration of sulfadiazine was stopped (and nine days from the time it was started), a faint erythema appeared on the face and trunk. There was a mild conjunctival injection. The temperature rose to 104 F. but dropped to normal the following day. On March 14 the eruption was generalized and consisted of discrete and confluent pink pea sized macules. It closely resembled the rash of measles. The tip of the spleen was felt at this time. On March 16 there was a bright red erythema involving the entire body with 10 to 12 flaccid bullae scattered on the trunk and extremities. The bullae varied from 1/2 to 3 inches in diameter and contained clear fluid. When the skin was pinched gently a new bulla was formed (positive Nikolsky sign). There were many ruptured bullae in the mouth and extensive denudation of the buccal and palpebral conjunctivas. On March 17 no sulfadiazine was detected in the blood, the nonprotein nitrogen was 33.6 mg. per hundred cubic centimeters and urinalysis revealed a trace of albumin and an occasional granular cast and red blood cell. The white blood count was 12,000 per cubic millimeter with 79 per cent polymorphonuclear leukocytes. New bullae continued to appear. The patient was extremely toxic and his temperature varied from 101 to 105 F. He was given large amounts of fluid including blood plasma and massive doses of ascorbic acid, nicotinic acid, thiamine hydrochloride and liver extract. The patient died on March 18.

COMMENT

The character of the eruption and its onset nine days after sulfadiazine therapy was started make it highly probable that it was a toxic manifestation of sulfadiazine medication. The resemblance to pemphigus was striking, although a definite erythema was present in areas not involved by bullae. This case shows that an erythematous eruption appearing after sulfadiazine therapy may be the first manifestation of a more serious dermatitis. Although sulfadiazine was not given after the eruption appeared (and not even a trace could be detected in the blood five days after cessation of the drug) the dermatitis continued to become more severe.

SUMMARY

A case of fatal, bullous dermatitis with involvement of the oral and conjunctival mucosae occurred after sulfadiazine therapy.

MEDICAL AND HOSPITAL MATERNITY AND INFANT CARE

FOR WIVES AND INFANTS OF ENLISTED MEN

EDWIN F. DAILY, MD

Director, Division of Health Services, Children's Bureau
U. S. Department of Labor

WASHINGTON, D. C.

The Congress has recently appropriated \$4,400,000 for continuing into the fiscal year beginning July 1, 1943 grants to states to provide medical, nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the United States under plans developed and administered by state health agencies and approved by the chief of the Children's Bureau.

This program, which received its first special appropriation in March 1943, is now operating in thirty-nine states, Hawaii, Alaska and the District of Columbia. The health agencies of several of the remaining nine states¹ are at the time this is written, completing their plans for administering these programs.

Thirty-three state health agencies reported 11,586 authorizations for medical and hospital care under this program during the month of June. More than 95 per cent of these authorizations were for maternity care and less than 5 per cent for pediatric care. The average amount obligated for the medical and hospital care of each case was approximately \$75. Reports received from thirty-eight state health agencies estimate that during the month of July maternity care will be authorized under this program for more than 20,000 wives of enlisted men.

The policies of administration which are of particular interest to physicians as summarized from the state plans approved by the Children's Bureau include the following:

WHO IS ELIGIBLE FOR THESE SERVICES?

The wife and infant of any enlisted man serving in the Army, Navy, Marine Corps or Coast Guard in the fourth, fifth, sixth or seventh pay grade are eligible as long as similar services are not readily available through medical or hospital facilities of the Army or Navy. (The Congress has recently made eligible for these services when circumstances require the wives and infants of enlisted men in the first second and third pay grades. Ninety-three per cent of enlisted men are in the fourth, fifth, sixth and seventh pay grades.)

WHERE MAY WIVES OF ENLISTED MEN SECURE APPLICATION FORMS?

Forms for requesting care have been made as readily available as possible for these families from state and local health and welfare agencies, American Red Cross chapters, antepartum clinics, military posts and local practicing physicians.

HOW ARE REQUESTS FOR AUTHORIZATION MADE?

The wife enters identifying data on the application form and takes it to the physician (private or clinic) of her choice. The physician completes the form and forwards it to the state director of maternal and child health (or his deputy), requesting authorization to provide the medical care needed at the rates of payment established by the state health agency. Physicians participating in the programs agree to provide the authorized services without charge to the patient or her family. Physicians and hospitals receive payment for authorized services from the state health agency only. Hospital care is authorized only when medical care is also authorized except when medical care is provided without cost to the patient or her family. For example, when a commissioned medical officer in the Army or Navy provides the medical care, the payment for hospital care can be authorized under the program. Payment is not made for services rendered to the patient prior to the date authorization was requested, except for emergencies. Care is usually authorized by the state health agency in the state in which the attending physician practices irrespective of whether the patient lives in the same state or in another state. The state health agency reviews the request for authorization and usually within twenty-four hours notifies the patient, physician and hospital whether authorization is granted. Each case is referred to the local health department for antepartum and postpartum public health nursing services.

WHAT SERVICES ARE AUTHORIZED AND WHAT RATES OF PAYMENT HAVE BEEN ESTABLISHED BY THE STATE HEALTH AGENCIES?

1 Complete medical care by the attending physician throughout pregnancy, labor and the postpartum period. Payments to the attending physicians for these services, including care of complications and operations performed by him, are made on a uniform inclusive rate basis in each state, varying between states from \$25 to \$50. In a few states the amount paid specialists in obstetrics may vary from one fourth to one third more than the amount paid general practitioners.

2 Medical care of sick infants during their first year of life. Payments to attending physicians are usually made on a visit basis with an average maximum of \$12 for the first week of illness and \$6 for each additional week of illness.

3 Hospital care as requested by the attending physician (if the hospital has been inspected and approved as meeting the requirements of the state health agency for maternity and pediatric service). Hospitals are usually paid at the inclusive ward cost per patient day as calculated annually by each hospital.

4 Consultation by recognized specialists. Lists of qualified consultants have been established in the states, and general practitioners are urged to call them for any serious complication. Consultants are paid at rates varying from \$5 to \$10 for bedside consultation and up to \$25 to \$50 when they perform major surgery at the request of the attending physician.

5 Bedside nursing care at home or in the hospital for seriously ill patients.

6 Ambulance service and unusually expensive drugs under some of the state programs.

The extent to which services are made available in each state and additional information relative to policies of administration may be secured from each state health agency.

The state health agencies have shouldered the responsibility for putting this program into operation without appropriation of additional administrative funds because the Congress did not make funds available for administration either by the state agencies or by the Children's Bureau. All expenditures from the appropriation are

¹ Colorado, Georgia, Louisiana, Massachusetts, North Dakota, Ohio, Oregon, Pennsylvania and Texas.

for medical, hospital and bedside nursing care. The wholehearted cooperative spirit which state agencies have shown in formulating plans and directing their execution has contributed greatly to the success in establishing and maintaining these programs. The cooperation of practicing physicians and hospital administrators, on whom much of the burden of the program ultimately rests, has made it possible for most of the state health agencies to establish these statewide services for the wives and infants of enlisted men in the armed forces.

PROBLEMS OF HOSPITAL ORGANIZATION PRESENTED DURING THE DETROIT RACE RIOT

WILLIAM L. ABBOTT, M.D.
AND
JOHN WINSLOW HIRSHFELD, M.D.
DETROIT

The recent race riot presented the staff of the City of Detroit Receiving Hospital with the problem of caring for 433 new patients in twenty-four hours. In addition, the load of new patients during the six to twelve hour periods immediately preceding and following these twenty-four hours was heavier than usual. We do not intend to give a detailed account of the diagnosis and treatment of these cases but rather to discuss the organization for the handling of such a large number of cases.

Patients Admitted to Emergency Ward on June 21
(Midnight to Midnight)

Stabbings	56
Gunshot	65
Beatings	312
Total casualties	433
Admitted to hospital	101
Treated in emergency ward and discharged	332
Died from wounds	17

The rioting began late Sunday, June 20, 1943 but patients were not admitted in large numbers until midnight. Of the 433 admitted to the emergency ward (table) from midnight Sunday to midnight Monday, June 21, 101, or approximately 24 per cent, were hospitalized. The remaining 332 patients required some sort of treatment, in many instances the suturing of multiple lacerations. Many of these patients who were severely injured but sent home after treatment would under less pressing circumstances have been hospitalized.

Weapons confiscated from the rioters included shotguns, rifles, revolvers, knives, razors, ice picks, blackjacks, meat cleavers, axes, hatchets, baseball bats and clubs, bricks, stones, hammers, bowling pins and bayonets. The injuries inflicted from this wide assortment of weapons were varied and often complex. During the twenty-four hour period twenty major operations were performed on patients suffering from bullet or stab wounds of the abdomen, thorax or extremities (including compound fractures) or suffering from depressed skull fractures. In addition, approximately seventeen fractures were reduced.

Seventeen patients died during the twenty-four hour period. Of these, 14 were either dead on admission

or died within ten to twenty minutes. Hence treatment was of no avail. Two of the 3 patients who survived for a longer period had serious depressed fractures of the skull. The other sustained a gunshot wound of the abdomen and did not respond sufficiently to shock treatment to permit exploration. Three patients succumbed postoperatively between 2 a.m. and 7 a.m. on Tuesday, June 22. It is possible that 1 or 2 of these 3 patients might have survived if better organization had permitted more complete postoperative observation.

One of the first persons to be killed was a physician attempting to make a house call in the district where the rioting was taking place. The cars of several other physicians were badly damaged by the rioters. Hence very few of the attending staff were able to come in, and the medical care was given almost entirely by the house staff of the Receiving Hospital.

Early in the course of the emergency it became apparent that the hospital would have to be cleared of all patients who could be moved. We therefore submitted a list to the hospital authorities, who in turn arranged for the patients' safe transportation. To increase further the capacity of the hospital, emergency beds were set up in lecture rooms and clinics. The quick exhaustion of the available blood and plasma in the hospital necessitated an additional amount, which was obtained from the American Legion plasma bank. A very large amount of surgical materials was required for treatment of the patients, and by the end of the twenty-four hour period the supply of certain items had been almost exhausted.

Since the Detroit Receiving Hospital is primarily designed to handle emergencies, it was felt previous to the riot that its organization was adequate to cope with a large influx of seriously injured patients. Consequently no special plan had been made to handle such a disaster. Although there was some confusion and duplication of effort, the organization was fairly efficient, and by and large the patients were well handled. A few patients were temporarily misplaced, and in at least 1 instance we feel that this misplacement may have contributed to the patient's death. The experience demonstrated clearly that even in a hospital devoted largely to emergency work the usual routine is not adequate to cope with a large influx of injured patients. If such an emergency is to be handled with proper efficiency, it is imperative to have a well organized plan of action. A schematic representation of such a plan is shown in the accompanying chart.

Because of the difficulty in getting to and from the hospital, it is necessary to make the institution almost entirely self sufficient. The methods outlined by Faxon and Churchill¹ which were employed at the Massachusetts General Hospital during the recent Cocoanut Grove disaster would not have been entirely satisfactory in our emergency because they depended on summoning outside assistance. In the second place, disasters resulting from fire and explosion are usually self limited, while in rioting it is possible that the flow of casualties may continue for some time as in actual warfare.

Our experience, however, emphasizes the importance of some of the features of Faxon and Churchill's plan.

1. The immediate examination and segregation of the living and the dead and of major and minor cases.

From the Department of Surgery, Wayne University College of Medicine and the Surgical Service of Receiving Hospital, Detroit

1. Faxon, N. W., and Churchill, E. D. The Cocoanut Grove Disaster in Boston, J. A. M. A. 120: 1385-1388 (Dec. 26) 1942.

Because of the complexity of injuries it is important that this function be performed by a physician of considerable experience

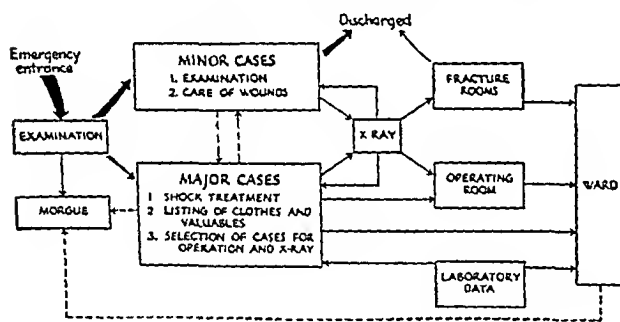

2 The organization and division of the hospital personnel into teams to care for the registration of patients, the identification and tagging of living and dead, the care of clothing and valuables, the thorough examination of patients and the care of minor wounds, the treatment of shock and the selection of patients for operation and x-ray examination, operative and postoperative care of patients and the performance of essential laboratory tests

3 The concentration of serious casualties into one group so that they can be under constant supervision

The experience gained during the recent race riot emphasized the following additional problems

1 During an emergency of long duration there is need for replenishing linens and other supplies. If because of street rioting or the disruption of transportation it is impossible to bring additional aid to the hospital, volunteer workers should be assembled in previously designated spots for the preparation of materials and supplies to be taken to the hospital under suitable military protection

2 Any such plan should provide relief for the hospital personnel so that food and rest may be obtained

Plan for handling a large number of injured patients

3 While riots and such disasters are rare, when they do strike it is frequently necessary to send equipment from one hospital to another. The multiplicity of design of transfusion sets makes such an interchange difficult and time consuming. It would therefore be desirable to standardize equipment to make it interchangeable

4 It is well known that many hospitals have not been laid out in a fashion commensurate with the most efficient handling of patients. Under normal conditions the increased amount of transportation necessitated by inefficient hospital layout is not noticed, but the sudden influx of a large number of seriously injured patients immediately demonstrates the desirability of having the distance between emergency ward, x-ray department, operating rooms, recovery ward and the plasma bank as short as possible

In conclusion we should like to reemphasize the following points

1 There is need for a well rehearsed and well organized plan to cope with disasters, as time is not available for organization when an emergency occurs

2 The plan should organize the available hospital personnel into teams for definite duties at specific locations

3 The plan should provide for the classification and segregation of patients so that the teams can care for them with the utmost efficiency

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT

AUSTIN E SMITH M.D. Secretary

ENTERIC COATED DOSAGE FORMS OF DIETHYLSTILBESTROL NOT ACCEPTABLE FOR N N R

In the consideration of various submitted dosage forms of diethylstilbestrol, the Council reached the conclusion that there was no conclusive evidence to show that the use of enteric coated dosage forms decreased the incidence of such symptoms of toxicity as nausea, vomiting and the like. Interested firms were informed of this decision of the Council and none offered any evidence to establish the need for marketing diethylstilbestrol in enteric coated dosage forms as superior to the plain dosage forms, from the standpoint of stability, therapeutic efficiency or incidence of toxicity symptoms

The Council therefore authorized publication of the foregoing statement to place itself on record in this matter

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTIONS WILL BE SENT ON APPLICATION

AUSTIN E SMITH M.D. Secretary

DIETHYLSTILBESTROL (See the Supplement to New and Nonofficial Remedies, 1942 p 27)

The following additional dosage forms have been accepted
E R SQUIBB & SONS, NEW YORK

Tablets Diethylstilbestrol 0.25 mg

LEDERLE LABORATORIES, INC., PEARL RIVER, NEW YORK

Ampuls Diethylstilbestrol (in sesame oil), 0.5 mg per 0.5 cc 0.5 cc

Ampuls Diethylstilbestrol (in sesame oil), 0.1 mg per cc 1 cc

Capsules Diethylstilbestrol 0.1 mg 0.5 mg and 1.0 mg

THEOPHYLLINE WITH ETHYLENEDIAMINE (See New and Nonofficial Remedies 1942 p 332)

SATURDAY, JULY 31 1943

PRACTICE OF RADIOLOGY AND
HOSPITAL SERVICE PLANS

Among the problems especially considered by the House of Delegates at the meeting of the American Medical Association in Chicago in June, few have aroused more interest or concern than the place of radiology in new forms of hospitalization insurance as well as its place in routine hospital service. The question was brought before the House as a result of three resolutions introduced at the Atlantic City session in 1942. These resolutions were referred to the Board of Trustees for clarification as to existing relations between physicians and hospitals. The supplementary report of the Board of Trustees pointed out that all the questions involved in the same or similar form had previously been considered and acted on by the House of Delegates. Specific citations were made to the previous actions of the House on this subject.

The reports were assigned by the speaker of the House of Delegates to the Reference Committee on Reports of Board of Trustees and Secretary. The reference committee, after reviewing the two supplementary reports of the Board of Trustees, made the following recommendations:

A That the House emphatically reiterate that it disapproves the injecting of a third party into the personal relationship of the patient and the physician, and that hospitals should not be permitted to practice medicine.

B That the practice of radiology, pathology and anesthesiology is the practice of medicine just as much as is the practice of surgery or internal medicine, and that it is only a short step from including the first three in a medical service plan to including the whole field of medicine in such a plan.

C That the public should be educated to realize that the hospital created monopoly control of radiologic or any service as a source of profit beyond the normal provision for replacement, department development and proper proportion of over-all costs of operation of the hospital should not be permitted, nor can the hospital rightfully use per diem charges against all the hospital patients to support a radiologic or other department devoted to creating bargains in radiologic or other services in order to make hospital group insurance more attractive. To permit either will result in decrease of the quality of service and increased cost to the patient.

D The medical profession must watch with care all proposed plans for medical service and endeavor to prevent the acceptance of any plan which includes medical service under the control of the hospital.

E The effectiveness of this program can be attained only if constituent state medical associations and component county medical societies use their influence on hospitals in their respective localities and exercise control over the local members of the medical profession.

F The public must be educated on what it will mean to them in the way of inferior medical care if these dangerous trends are not curbed.

G In the relationships of the medical staff and the board of directors of a hospital there should be no intermediary. The staff should have direct access to the board.

H The Board of Trustees should continue its conferences with national hospital associations and should also endeavor to enlist the support of special medical organizations in education both of the profession and of the public.

The Board of Trustees in general and Dr. Sensemich and Dr. Irons in particular should be commended for the tremendous amount of time and effort which they have given in preparing their very informative report.

Your reference committee recommends that the House of Delegates of the American Medical Association urge the American Hospital Association to withhold approval of the uniform comprehensive Blue Cross contract proposed by the Hospital Service Plan Commission of the American Hospital Association which includes certain medical services as a part of hospital care and which, if adopted as recommended by the said commission, would virtually compel the addition of medical services to the benefits of those Blue Cross plans and now accede to the demands of the American Medical Association by confining their benefits to hospital services.

In presenting this report to the House of Delegates, Dr. Louis H. Bauer, the chairman of the reference committee, made some interesting comments which should be considered carefully by every physician. These supplementary reports of the Board of Trustees present an analysis of current trends in the nature of medical practice which may have a profound effect on the whole future of medical service. The reference committee said:

Unless the medical profession as a whole is willing to devote at least the same amount of time and effort in studying the report and correcting the dangers pointed out therein as the Board of Trustees has in compiling it, then we might as well "throw in the sponge" now and consent to lay domination of the practice of medicine.

In the report of the reference committee it was indicated that the "Blue Cross" plans to give medical service with or without the approval of the medical profession. This prediction has already been demonstrated to be a practice in many parts of the country. An announcement just made by the Associated Hospital Plan in New York City states plainly the intention and the conditions under which services will be rendered. The report of the reference committee recognizes the bald outlines of the situation when it says: "The fact that the House of Delegates on numerous occasions has declared against the selling of medical service by hospitals has not stopped the practice." The

treatment recommended for the cure of this unfortunate situation is also succinctly stated by the reference committee when it says "National approval or disapproval of any practice is a waste of time unless the state and county organizations will see that the dicta of the national body are carried out in the small localities."

The majority of roentgenologists of the United States and their national organizations are convinced that the subscribers contract in hospitalization insurance should exclude all medical services and that contract provision should be limited exclusively to hospital facilities. The action of the House of Delegates taken in 1934 emphasized that all features of medical service in any method of medical practice should be under the control of the medical profession and that hospital service and medical service should be considered separately. Again in 1936 the House of Delegates emphasized its interpretation of this point of view by saying, in accepting the report of a reference committee

If hospital service is limited to include only hospital room accommodations such as bed board, operating room, medicines, surgical dressings and general nursing care, the distinction between hospital service and medical service will be clear.

In the report of the reference committee this year, this point is further stressed in paragraphs C, D and G cited in this editorial. These paragraphs indicate the technics by which those who are concerned may aid in reversing or inhibiting a trend which is apparently now well under way in regard to radiologic practice. Education of the public as to the significance of radiologic practice is important in this direction. Doubtless few of those who obtain the services of radiology in hospitals realize that in many institutions the radiologist is working for a small salary and the hospital is deriving a considerable profit from his professional practice. In other institutions what amounts to virtual fee splitting between the hospital and the radiologist is routine technique. Certainly it is not to the interest of the patient, who must be given first consideration, that the necessity for radiologic study of his case should be made the occasion for providing excess income for the hospital. If the trend is to be controlled, every new arrangement between a hospital and a radiologist and every new plan for a prepaid medical service should be carefully scanned by the county medical society in the area concerned to determine whether or not it violates the fundamental tenets that have been so often iterated and reiterated by the House of Delegates of the American Medical Association. The danger to the sick does not lie in the collection of income for the hospital or the radiologist; it is in the inevitable deterioration that must come in any form of medical service when its practitioners are placed on a basis in which the quality of the service rendered is secondary to the price charged or the method by which the service is supplied.

THE TREATMENT OF TUMORS WITH ESCHAROTICS

A report in a recent issue of the *Journal of the Missouri State Medical Association* by Ackerman and Eberhard¹ calls attention again to the dangers of the use of escharotic pastes in the treatment of cancer. The 39 patients who constitute the basis for their report were treated previous to their admission to the Ellis Fischel State Cancer Hospital by various charlatans who used the paste treatment. Nineteen of the patients had received treatment at Dr. Nichols' Sanatorium, Savannah, Mo. This institution was investigated and its practices were condemned by THE JOURNAL in 1933. The lesions of the 39 patients treated with paste included 23 which were located on the skin of the face and the lip, 2 on the skin of the hand, 1 on the vulva, 1 on the cervix and 12 on the breast.

The deplorable results of the treatment may be best surmised from the consideration of the 12 patients with breast tumor. Ten of these showed evidence on admission to the State Cancer Hospital of local recurrence and metastasis. Two of the patients with lesions of the breast did not have evidence of tumor but showed absence of the breast and extensive surrounding disfigurement. The clinical histories of these 2 patients suggested that the original lesion was in all probability benign.

Ackerman and Eberhard raise the question whether "chemosurgery"—a method advocated by Mohs—has any place in the treatment of tumors. Mohs² in 1941 published an enthusiastic report on the treatment of 440 patients with primary carcinoma located on the face, eyelids, lips, nose, ear, parotid gland, penis, breast, vulva and vagina. The treatment consisted in the application of a zinc chloride paste, which was followed twenty-four hours later by the surgical removal of that part of the tumor which was 'fixed' by the zinc paste. A further application of the escharotic paste was practiced until careful microscopic control of the underlying tissue established the total destruction of the malignant growth. This rather painstaking piece of clinical investigation failed to arouse much interest on the part of the medical profession. Ackerman and Eberhard believe that this chemosurgical method accomplishes nothing that cannot be equally well, or better, done by irradiation or surgery. They do not believe that the method has a practical place in the treatment of superficial lesions readily controlled by irradiation or surgery or of deep seated visceral tumors. They feel that it certainly should never be used in the treatment of breast tumors. The method at best can hardly compete with the precision and effectiveness of modern radiation therapy.

POSTWAR PLANNING FOR CANCER CONTROL

What can be done to control cancer more and more effectively in the years to come? Unremitting promotion of research on cancer, better education about cancer, more facilities for diagnosis and treatment of cancer—the basic elements in control of cancer—should greatly improve the situation.

The only hope of solving fundamental problems of cancer lies in research. But the immediate needs of the cancer patient are not met with the promises of research. The patient must be treated as well as possible with the means at hand. Consequently clinical research on cancer—observational, diagnostic, surgical, radiologic—must be intensified. Here is a vast field for continued progress by clinicians and pathologists. An urgent need is research into the incidence and characteristics of cancer in different areas and environments. Studies must be made of social and economic aspects with a view to providing adequate services for all types of patients. What are the trends and needs of cancer in a given city, community or geographic area? Plans should be made to answer such questions on the basis of results of local studies, and ways should be devised to meet the needs by the organized cooperation of the agencies concerned, medical, health and social.

The means at hand for the immediate control of cancer are the application of knowledge to its prevention and its best treatment as early as possible. The first step toward diagnosis must be taken by the patient. At present he cannot be sought out as in tuberculosis. There is no accepted test of immunity or susceptibility to cancer. The earliest time when cancer can be treated is, most always, when the patient comes to the physician of his own will, often this is late. A personal knowledge of cancer by every one, an understanding of its earliest manifestations, is a vital factor for more efficient control. The delay in the treatment of cancer, the weeks and months that only too commonly intervene between the first symptoms and treatment, emphasize the need of planning for more and better education.

Does cancer education as now conducted teach as many people as it should and is the education sufficiently continuous and personalized? In cancer of the uterus and of the breast, education appears to be reducing the time between the first signs of the disease and treatment as reflected in the reduction in the rates of cure and of death of those cancers. In other accessible cancer, for example the larynx, the delay is still far too long in many cases.

Lack of early action by the patient is not, however, the only difficulty in control of cancer. There may also be lack of competent treatment within easy reach. In cancer, self-supporting patients of moderate means may need help as do the indigent. The many cases of

accessible, curable cancer that somehow slip into as yet incurable stages everywhere demonstrate the needs for earlier and better treatment of cancer, needs that can be met only by careful planning by states and communities.

On every practitioner in every branch of clinical medicine rests the responsibility of finding cancer in his patients when it is present and of doing what he can to prevent cancer by the elimination of "irritative" and inflammatory conditions. The education of physicians about cancer will remain the duty of medical schools, hospitals, tumor clinics, medical organizations, medical publications and governmental agencies. The plans for cooperation in these matters must recognize the tendency of diagnosis and treatment of cancer to develop into a specialty or specialties requiring special training and special facilities.

The organization of encouragement and facilities for periodic health surveys for cancer in general and particularly for cancer of the uterus, the breast and the stomach demands careful planning. Group examinations may provide better possibilities for prevention and early diagnosis than are otherwise available for many people. The cost of expert periodic examinations decreases with increase in the number of subjects examined, since it permits better utilization of time and materials. The manifest usefulness of diagnostic and preventive cancer clinics, when properly organized, should lead to the consideration of plans for their establishment in areas where the need is manifest.

The problem of cancer among veterans of the war needs special study. A permanent, closed group of this type offers suitable conditions for systematic control by continuous personal education, by periodic examinations and by early diagnosis and treatment. According to William H. Donner,¹ an average of twenty-two veterans of the first world war entered hospitals of the Veterans Administration each day in 1941 with cancer. Donner says that "it is only reasonable to expect that, twenty or twenty-five years from now, about forty-five veterans of the second world war will daily enter Veterans hospitals with new cases of cancer." Already cases of cancer of the breast in women on war service have come to the attention of the Veterans Administration, which faces the unique opportunity to institute systematic, personalized cancer control on a gigantic scale under the most favorable auspices.

In all plans for the control of cancer among various groups of our population the medical profession must play a conspicuous role. In the absence of special facilities the burden rests particularly on the general practitioner, the public health officials, the pathologists, the surgeons and experts in radiology. Scientific planning can determine just how the most efficient utilization of personnel and materials is to be secured.

¹ International Cancer Research Foundation, Report for 1942, p. 11

Current Comment

TOXICITY OF INSECTICIDES

Poisonings following the accidental or intentional ingestion of insecticidal preparations have been frequently reported. Deaths have probably occurred. An acute fatal illness which followed the use of a spray to exterminate bedbugs has recently been reported¹ to THE JOURNAL. Reply from the manufacturer after inquiry concerning the composition of the preparation included the following: "Under the regulations of the Insecticide Act of 1910, whenever an insecticide does not contain a list of the percentage of active or inert ingredients it is construed as being 100 per cent active. We regret that the policy of our company does not permit us to divulge the formula of any product." Under existing regulations active and toxic ingredients can be secretly incorporated in insecticides without disclosing their nature and thereby subjecting the users to great hazards. Remedial measures designed to require the proper labeling and other safeguards similar to those which have been adopted for drugs now appear to be urgently necessary.

ALDOUS HUXLEY'S VISION

Mr Aldous Huxley's widely advertised new book "The Art of Seeing" and his magazine articles have brought new interest in certain unorthodox methods of treating visual defects which seemed to be en route to desuetude. The story¹ in brief is that Mr Huxley, basing his conclusions on his own experiences has revived the theories of William H Bates. Bates, years ago, presented some animal experiments by which he claimed to have shown that accommodation in animals and man was due to the action of the superior and inferior oblique muscles and deformation of the eyeball, the universal treatment for which is the institution of "dynamic relaxation." This was to be accomplished by certain exercises, as a result of which the eye would become normal. Huxley maintains—and there is no reason to doubt his statement—that following an attack of keratitis punctata at 16 he followed orthodox methods of treatment with glasses for twenty-five years. His vision nevertheless became progressively more deficient until he began the Bates method of visual reeducation by eye exercises. "In two months," he then said, "I was reading without spectacles." Two possible explanations have so far been proposed: an ingenious and complicated reconstruction of the sequence of possible organic events presented by Hamilton Hartridge, professor of physiology in the University of London, and the obvious possibility of a rapid functional recovery. Regardless of the actuality of these explanations it is certain, as Duke-Elder points out, that this method may be dangerous when prescribed for one who suffers

from glaucoma or detachment of the retina or for a myopic child, even though it was as satisfactory for the simple neurotic as any other system of Yoga or Coue-ism. The majority of intelligent persons with access to competent ophthalmologists will not permit themselves so long to be deceived by pursuing this method. Unfortunately, many a credulous victim will throw away his glasses in search of perfect sight by this technic and thereafter find himself even worse crippled in eyesight than previously.

MICROBES IN NATURAL HABITATS

In his presidential address before the Society of American Bacteriologists Waksman² discussed the relationships of microbes in their natural habitats as distinguished from their isolation and activities in pure cultures. In dealing with pathogenic microbes or with microbes used for various purposes in industry or in the preparation of foodstuffs pure cultures are essential. But the pure culture is not adequate in the study of microbic life in soil waters, plant and animal residues, and other substrates. The great majority of microbes carry out their activities in mixed populations in which the reactions of a particular microbe may differ greatly from those in pure culture unaffected by the presence of other microbes. Waksman, a soil microbiologist, draws on the microbic life of the soil for illustrations of the relationships of microbes in natural conditions. The microbe population of the soil includes "thousands of species of bacteria, hundreds of genera of fungi, actinomycetes and algae, numerous families of protozoa, nematodes, and other worms and insects", probably also a great many viruses. Some soil microbes are concerned with highly specific reactions, e.g. fixation of atmospheric nitrogen, production of nitrite from ammonia and many others. Certain processes of this kind are carried out by a number of different organisms. Some of the processes take place in chainlike reactions in which one organism acts on the products of another. Decomposition of proteins or of cellulose is an example of this mode of action. Microbes in the soil appear not only to assist one another or to compete with one another but also to produce stimulating as well as directly injurious substances and effects. There is now an extensive literature on the results of research in this fertile field. Light has been shed on complex natural processes. The research dealing with the antagonistic relations of micro-organisms is yielding results of practical significance. The production of antibiotic substances is of great importance in mixed microbic populations. Mixed cultures were early found to be antagonistic to pathogenic bacteria. Typhoid bacilli are destroyed by organisms in sewage soil and water. Antibiotic substances may be produced by soil organisms on artificial mediums and also obtained by extraction of such organisms. Their effects vary: some act on many, some

on only few microbes, some act on fungi, others on bacteria (penicillin, tyrothricin, gramicidin), they may influence cell division, respiration metabolism. Waksman states by way of summary that these antibiotic substances have many important practical applications, including "(a) the domestication of micro-organisms for disease control, (b) the isolation of new chemotherapeutic agents for combating animal [and human] diseases, (c) the utilization of the activities of micro-organisms for combating certain plant diseases." The address gives a good bird's eye view of the struggles for existence in the world of microbes and of the dynamics of microbial populations.

SUDDEN DEATH FROM ALLERGIC SHOCK

A remarkable case of sudden death from allergic or anaphylactic shock is reported by Hunt,¹ who had charge of the medicolegal examination. The main details of the case are recounted on account of the warning it conveys to physicians. In a hospital for the insane a study was to be made of the rate of the cutaneous spread of color in schizophrenic as compared with normal persons. The test substance selected was guinea pig hemoglobin under the mistaken idea that it would be safe because of its supposed low antigenic power. It is not stated in the report how the hemoglobin was prepared or whether special efforts had been made to eliminate other blood proteins. Here the question arises why a foreign protein should be used to study the spread of color. Why not human hemoglobin? The guinea pig hemoglobin was dissolved in isotonic solution of sodium chloride "made up to a volume equivalent to that of the quantity of blood from which the corpuscles were originally derived," and of this solution 0.2 cc was injected intradermally. The normal controls in this experiment were young women who were questioned concerning allergic sensitiveness and previous immunization, to which negative replies were made in all cases. Physical examinations and eye and scratch tests were not made, since they were not thought necessary. One wonders how abnormal sensitiveness could have been excluded in the schizophrenic patients. A well developed woman of 22 became dyspneic and cyanotic, and in spite of the injection of epinephrine into the heart and artificial respiration she died ten minutes after the injection of guinea pig hemoglobin into the skin of the right forearm. The postmortem examination the results of which are described fully in another paper,² brought forth no other explanation of death than allergic shock, and the Prausnitz-Küstner reaction, a local passive sensitization, revealed the presence in the blood of the dead woman of antibody specific for some component of guinea pig blood. Closer inquiry disclosed that the mother of the subject of this report had asthmatic attacks and symptoms of hay fever, that a brother suffered from hay fever and that the mother's first cousin, also asthmatic, at the age of 16 died ten minutes after the sub-

cutaneous injection of diphtheria antitoxin, the first death of that kind in this country.³ The lesson again brought home by the bare facts in Dr. Hunt's report is that the most watchful precaution must always be taken to avoid fatal shock on the injection of foreign protein antigenic material into human beings.

CANCER OF THE STOMACH

The entire June issue of the *Archives of Surgery* is devoted to articles on various aspects of gastric carcinoma. Among the subjects discussed are experimental gastric carcinoma, relations between chronic atrophic gastritis and cancer of the stomach, metabolic abnormalities in patients with cancer of the gastrointestinal tract, diagnosis and surgical care of patients before and after operation, transthoracic resection for cancer, and prognosis and end results in the treatment of cancer of the stomach. The contributors include some of the most experienced workers, and the entire number therefore constitutes an up to date evaluation of present knowledge in the field.

PROVISIONAL BIRTH AND DEATH STATISTICS IN 1943

The rise in the birth rate in the United States became notably accelerated in the fall of 1942, preliminary figures¹ indicate that the rate has been continued at a high level for the first four months of this year although there has been a slight drop in the percentage increase in the monthly birth rates in comparison with the corresponding months of 1942. Based on figures for the first four months of 1943 the provisional annual crude birth rate is 22.1 per thousand of estimated population as compared with a rate of 19.2 for the same period of last year. It may be anticipated that as the war progresses the rise in crude birth rate will first decelerate and later decline. The death rate beginning in September 1942 also was higher than the rate for the corresponding months in 1941, and the crude death rate in 1943 has so far continued higher than in the early months of 1942. Sampling figures taken in March 1943 indicate that pneumonia and influenza mortality for the first quarter of 1943 was 10 per cent higher than last year, the rate for infectious enteric diseases was 15 per cent higher, that for the common diseases of childhood was 10 per cent higher and that for syphilis 11 per cent higher. The figures for deaths from cerebrospinal meningitis, which were sharply higher in the first months of 1943 than in 1942, are the only ones, however, which might be clearly interpreted as significant. The interpretation of these provisional figures must be cautious, but the facts themselves may sometimes furnish interesting clues to long or short term trends.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

THE FINNEY GENERAL HOSPITAL

The Finney General Hospital was formally opened for patients on June 16 after having been activated on April 20. The hospital, located at Thomasville, Ga., has a setting of the Old South with brick pillars and a white wooden fence at the main entrance. A $\frac{1}{4}$ mile driveway leads through yellow pines to the Headquarters Building with its white columns and flanked by evergreens and boxwood. Throughout the spacious grounds are found numerous dogwood trees, crape myrtle and pine.

This 1,800 bed hospital is of the cantonment type. The officers' quarters, barracks and warehouses are composed of hollow tile, while the wards and connecting corridors are of gypsum board.

The commanding officer is Col. Samuel M. Browne of Anderson, S. C., and the executive officer is Lieut. Col. James T. McGibony of Greensboro, Ga. Colonel Browne has been in

Administration building, Finney General Hospital, Thomasville, Ga.

the Army Medical Corps for twenty-seven years. He spent two years in France from 1929 to 1931. He was with the American forces in China. Prior to being ordered as commanding officer of the Finney General Hospital, Colonel Browne was chief of the medical service, Panama Canal Department, special detail with the governor of the Panama Canal and with Gorgas Hospital. Colonel McGibony is a graduate of the Army Medical School, Washington, D. C., and Carlisle Barracks, Pennsylvania. Colonel McGibony was on duty in the Surgeon General's Office in Washington before being assigned as executive officer at Finney General Hospital.

The Finney General Hospital is named in honor of the late Brig. Gen. John Miller Turpin Finney (June 20, 1863-May 30, 1942), one of America's most distinguished surgeons. General Finney maintained a keen interest in and participated actively in military affairs. He was brigade surgeon of the Maryland National Guard from 1898 to 1904 and was commissioned in the Medical Reserve Corps in 1908. He was clinical professor of surgery at Johns Hopkins School of Medicine when he went abroad in 1917 as commanding officer of Base Hospital No. 18. In France, General Finney was appointed director of surgery for the American Expeditionary Forces. He was awarded the

Distinguished Service Medal for the organization of surgical teams for the purpose of affording expert surgical aid to the wounded in the immediate vicinity of the battlefield. Dr. Finney received many honors. He was honorary member of the Hunterian Society of London, the Medical Society of London, the Royal College of Surgeons in England, the Royal College of Surgeons in Ireland, the Royal College of Surgeons in Edinburgh and received honorary LL.D.s from Tulane University, Harvard University and Loyola College of Baltimore. He was one of the founders and first president of the American College of Surgeons, a member of the American Surgical Association, the Southern Surgical Association, the Medical and Chirurgical Faculty of Maryland and the Society of Clinical Surgery. Among the additional officers assigned to Finney General Hospital as of June 20 were:

Col. Samuel M. Browne, commanding officer
Lieut. Col. James T. McGibony, executive officer, medical inspector
Lieut. Col. Hugh L. McCallip, assistant medical inspector, Yazoo City, Miss.
1st Lieut. Frank E. Jones, sanitary engineer, Detroit

SURGICAL DIVISION

Major Crenshaw D. Briggs, director of the surgical division, Washington, D. C.
Major Wilford B. Hatcher, assistant director of the surgical division, Macon, Ga.
Major George T. McCutchen, chief of the general surgical branch, Columbia, S. C.
Major Thomas R. Gaines, chief of the eye, ear, nose and throat branch, Anderson, S. C.
Major Jacob Grove, chief of the genitourinary branch, Chicago.
Major Arthur J. Barlow, faciomaxillary plastic surgery branch, New York.
Capt. Everett I. Bugg, chief of the orthopedic branch, Durham, N. C.
Capt. Moyses P. Harnet, chief of the septic surgery branch, New Bedford, Mass.
Capt. Joel Hartley, orthopedic branch, New York.
Capt. Albert Faulconer, chief of the anesthesia and operating branch, Detroit.
Capt. Leslie M. Jones, anesthesia and operating branch, Detroit.
Capt. William T. Ladd, chief of the women's branch, Washington, D. C.
1st Lieut. Thomas A. Peterou, orthopedic branch, Savannah, Ga.

MEDICAL DIVISION

Major Hilton S. Read, director of the medical division, Atlantic City, N. J.
Major Howard D. Fabing, chief of the neuropsychiatric branch, Cincinnati.
Capt. Michael (NMI) Gleason, ward officer, communicable diseases branch, Mendota, Ill.
Capt. Paul M. Glenn, chief of the gastroenterology branch, Cleveland.
Capt. A. G. Hollander, chief of the cardiovascular-renal branch, assistant director of the medical division, Brooklyn.

LABORATORY DIVISION

Lieut. Col. Charles G. Darlington, laboratory division, New York.
1st Lieut. Alexander K. Prentiss, sanitary corps, bacteriologist, Cincinnati.
2d Lieut. Seth W. Gulkerson, sanitary corps, bacteriologist, Louisville, Ky.

OUTPATIENT DIVISION

Major George R. Dillinger, director of the outpatient division, admission and disposition officer, French Lick, Ind.
Major Joseph Killebrew, assistant admission and disposition officer, outpatient division, Chattanooga, Tenn.
Major Daniel Landrum, assistant outpatient division, San Juan, P. R.

ROENTGENOLOGIC DIVISION

Capt. Holart H. Wright, M. C., director of the roentgenologic division, Milwaukee.
1st Lieut. Joseph McKim, M. C., roentgenologist, roentgenologic division, Rite Spring, Minn.

AVIATION MEDICAL EXAMINERS

Graduation exercises were held at the School of Aviation Medicine, Randolph Field, Texas, on June 3, following completion of the course for Aviation Medical Examiners. The didactic portion of the course is conducted at Randolph Field, Texas, and the practical portion of the course at the three army air forces classification centers. The list of students graduating on June 3 follows:

ALABAMA

Thomas E Booth, 1st Lieut, Mont
gomery
William H DeRamus, Captain,
Shuin
Roy I Grubbs Jr, 1st Lieut
Luttrell
James T Jackson, 1st Lieut
Montgomery
Claude W Lavender, 1st Lieut

AWARDED LEGION OF MERIT

The War Department announced on July 15 an award of the Legion of Merit to Col Austin J Canning M C, U S Army for exceptionally meritorious service in the performance of outstanding service as commanding officer, Station Hospital Schofield Barracks (now known as North Sector General Hospital), in planning and coordinating the expansion of that hospital. During the period commencing Dec 7, 1941 his performance of duty in establishing and carrying out the handling of battle casualties contributed in a large measure to the saving of a large percentage of such casualties. Colonel Canning graduated from the University of Pennsylvania School of Medicine Philadelphia in 1911 and from the Army Medical School in 1914.

Col Clarence E Fronk of the Army Medical Department has been awarded the Legion of Merit for exceptionally meritorious service as assistant (liaison officer) to the department surgeon Hawaiian Department during the period Feb 13 1941 to April 11 1941 in connection with the formulation of plans for the initiation of civilian medical defense measures and in presenting these plans to and having them accepted by local civilian agencies and authority. His energy experience and knowledge of local conditions were of the greatest value and contributed materially to stimulating the initiation and development of civilian medical defense measures largely volunteer at a time when such action was most necessary. Colonel Fronk graduated from St Louis University School of Medicine in 1906.

Col Alvin C Miller M C U S Army was awarded the Legion of Merit for exceptionally meritorious service in the performance of outstanding service as commanding officer, Tripler General Hospital in maintaining efficient hospital facilities on and after Dec 7 1941 reflecting great credit on the military establishment through the exceptionally prompt handling of a large number of wounded admitted within a brief period following the Japanese attack on Oahu, thus contributing in a large measure to the saving of an unusually high proportion of such casualties. Colonel Miller graduated from the Medical College of Ohio Cincinnati, in 1909 and from the Army Medical School in 1912.

Lieut Col (then Major) Leonard D Heaton M C U S Army was awarded the Legion of Merit for exceptionally meritorious service in the performance of outstanding service as chief of the surgical service North Sector General Hospital at the time of the Japanese attack on Hawaii on Dec 7 1941 and the months that followed. Lieutenant Colonel Heaton by his unusual devotion to duty and his excellent judgment at the time of the sudden emergency on Dec 7 1941 did much to enhance the efficiency state of readiness and effectiveness of the surgical teams handling that emergency and by so doing rendered service of great value. Lieutenant Colonel Heaton graduated from the University of Louisville School of Medicine in 1926 from the Army Medical School in 1929 and from the Medical Field Service School in 1929.

Lieut Col Charles T Young M C U S Army was awarded the Legion of Merit for exceptionally meritorious service in the performance of duty during, and after the Japanese attack on Oahu Dec 7 1941. Lieutenant Colonel Young, then chief of the medical service took over the supervision of all surgical wards and expeditiously organized and controlled the entire ward service for the preoperative and postoperative care of the wounded thereby making emergency therapeutic measures quickly available to battle casualties and contributing largely to the saving of lives. For his excellent judgment and thorough adaptability to these unusual duties he reflected great credit on the Medical Corps United States Army. Lieutenant Colonel Young graduated from Johns Hopkins University School of Medicine in 1927 and from the Army Medical School and Army Field Service School in 1929.

ONE THOUSAND CIVILIAN EMPLOYEES TREATED DAILY BY WAR DEPARTMENT

The War Department announced on July 2 that an average of 1,000 of its civilian employees in Washington apply for medical treatment or advice daily in War Department emergency rooms. During May, 2,751 patients were treated and 555 were sent home as unfit for duty. There were 1,450 employees injured on duty, mostly minor injuries, who were treated in emergency rooms. Only 38 of these were sent to the United States Public Health Service. Patients whose attendance records are faulty are examined in the emergency rooms to determine their fitness for duty. Physicians also examine individuals who apply for parking space near entrances because of physical disabilities. Staff physicians have completed 4,646 chest x-ray examinations, and are handling 200 a day. Arrangements have been made with state and city health units for care and home supervision of any tuberculous persons found. The facilities of the George Washington University Hospital Medical School have been offered for treatment of some cases of lung and heart disease found by War Department doctors.

The yearly per capita cost of treating the 44,000 civilian employees of the War Department amounts to \$2.37. Lieut. Col. A. J. Lanza, chief of the Occupational Hygiene Branch, Office of the Surgeon General of the Army, states that the amount allowed annually for this purpose in private industry commonly ranges from \$5 to \$10 per capita.

COLONEL HUME APPOINTED HEALTH OFFICER OF OCCUPIED SICILY

In an Associated Press dispatch from the allied headquarters in North Africa on July 18 concerning Gen. Harold Alexander's proclamation to the people of Sicily as military governor for the Allies of that island, it was pointed out that several AMGOT (Allied Military Government of Occupied Territory) leaders were already in Sicily or preparing to go soon in connection with the establishment of military government on that

island, among those named in this category was Col. Edgar E. Hume of the Army Medical Corps, who was listed to be chief American health officer. Colonel Hume graduated from Johns Hopkins University School of Medicine in 1913 and entered the Medical Reserve Corps as a first lieutenant on Sept. 16, 1916. He had been director of administration at the Medical Field Service School, Carlisle Barracks, Pa., since 1937.

APPOINTMENT OF MARRIED NURSES IN ARMY NURSE CORPS

For the duration of the war and for six months thereafter, married nurses who meet all other requirements for military service may now be accepted for appointment in the Army Nurse Corps as Reserve nurses. Only those nurses who are willing to accept assignment unreservedly will be appointed. A nurse with one or more dependent children under 14 years of age may not qualify for appointment.

LIEUT. EDITH E. GREENWOOD AWARDED SOLDIER'S MEDAL

The War Department announced on July 15 that Lieut. Edith E. Greenwood of North Dartmouth, Mass., was awarded the first Soldier's Medal ever made to a woman for her heroic conduct in saving her patients from a hospital fire at Yuma, Ariz., on April 17. A stove in the diet kitchen exploded and fire quickly spread through the ward, where Lieutenant Greenwood was duty nurse in charge of 15 bed patients. Lieutenant Greenwood gave the alarm and with the ward attendant, Pvt. 1st Class James J. Ford of Madrid, Iowa, tried to extinguish the flames. Finding that impossible, they removed all the patients safely. The rescue was speedily achieved and not a single patient was injured, although the ward burned to the ground in five minutes. Lieutenant Greenwood entered the army in September 1942, having completed her nurse's training at St. Luke's Hospital, New Bedford, Mass., in 1941.

NAVY

CAPT. ERIK G. HAKANSSON IN COM- MAND AT NAVAL MEDICAL RESEARCH INSTITUTE

Capt. Erik G. Hakansson, MC, USN, assumed command of the Naval Medical Research Institute, Bethesda, Md., on July 17, succeeding Rear Adm. William L. Mann, MC, USN, newly appointed medical officer for the Thirteenth Naval District. Captain Hakansson will supervise numerous scientific investigations which are being undertaken in the fields of naval medicine, surgery and hygiene. The projects under study include improvement of oxygenation, prevention of flash burns, provision of drinking water for sea castaways, nutrition, equipment for high altitude fliers and deep sea divers, and many others. Captain Hakansson is a specialist in tropical medicine and medical parasitology and has been on duty in the division of research, Bureau of Medicine and Surgery, since April 1942, when he was ordered to Washington from the U. S. hospital ship *Solace*. He graduated from the University of Illinois College of Medicine in 1915 and after an internship of two years he was commissioned in the medical corps of the navy as a lieutenant (jg). He was on duty in the Virgin Islands during the first world war organizing medical attendance for the inhabitants and modernizing hospital and sanitary services.

SHIP NAMED FOR DENTAL OFFICER

A new destroyer-escort vessel will be named in honor of the late Lieut. Comdr. Laurice A. Tatum (DC), USNR, who was killed in action on Sept. 15, 1942 while attached to the U. S. S. *Wasp* during the battle of the Solomons. The new escort vessel was launched on July 3 at Orange, Texas, with

Mrs. Cecile Cofield Tatum, widow of Dr. Tatum, as sponsor. Lieutenant Commander Tatum was awarded the Silver Star Medal posthumously on February 12. The citation was as follows:

"For extremely gallant and intrepid conduct while serving aboard the U. S. S. *Wasp* during the attack on that vessel by enemy Japanese forces. Completely cut off from the rest of the ship by raging flames, Lieutenant Commander Tatum calmly braved the danger from fire, exploding ammunition and flying debris to remain in the forecabin to administer first aid to all wounded in the vicinity. His great personal valor and courageous efforts on behalf of his shipmates, carried on only with improvised facilities, were in keeping with the highest traditions of the United States Naval Service."

MONTHLY CONFERENCE OF NAVAL MEDICAL RESEARCH INSTITUTE

The monthly conference held at the Naval Medical Research Institute, National Naval Medical Center, Bethesda, Md., on July 13 was attended by Rear Admiral E. R. Stitt, MC, USN, Ret., and Rear Admiral H. W. Smith, MC, USN, Ret., who spoke on the contributions of Admiral W. L. Mann Jr., MC, USN, to the field of medicine, naval hygiene and sanitation and naval medical research and was of the nature of a farewell to Admiral Mann on his detachment and departure to a new assignment as the incumbent president of the Association of Military Surgeons. These monthly conferences are informal and are designed for the interchange of ideas between outside scientists and the staff of the Naval Medical Research Institute.

PHOTOFLUOROSCOPIC CHEST EXAMINATIONS OF V-12 STUDENTS

The Bureau of Medicine and Surgery of the U S Navy, Washington, D C, announces that two new trucks equipped to make photofluoroscopic chest examinations have been procured for field use in connection with the V-12 Navy College Training Program for medical and dental students. One unit will be used in the East Coast and the other will cover the West Coast area. Arrangements are now being made to send these trucks to various training colleges in both coast areas to take chest pictures of all V-12 students.

SPECIAL LAPEL AND SLEEVE INSIGNIA FOR MEDICAL AND DENTAL STUDENTS

Special lapel and sleeve insignia have been authorized according to the Bureau of Medicine and Surgery for students in the Navy V-12 Program attending medical and dental colleges. Such students will wear the regular midshipmen's uniform. On the lapels of the blue uniform coat medical students will wear a device composed of the oak leaf and acorn insignia of the medical corps superimposed on a fouled anchor at a 45 degree angle. Similarly, dental students will wear the dental corps insignia superimposed on a fouled anchor. In addition the

number of years of completed medical or dental study will be indicated by gold sleeve stripes. These stripes, one for each year completed will be $1\frac{1}{2}$ inches long and $\frac{1}{8}$ inch wide. They will be sewed 2 inches above the cuff and at a 45 degree angle to the cuff line. First year medical or dental students will wear clean sleeves. When in khaki uniforms, medical and dental students will wear pin on insignia, similar to the lapel insignia on each side of the shirt collar.

AWARDED LEGION OF MERIT

Lieut Harold A Cassady, MC USNR, was awarded the Legion of Merit for exceptionally meritorious conduct in the performance of outstanding services as medical officer of a beach party during the assault on and occupation of French Morocco from Nov 8 to 11, 1942. With utter disregard for his own personal safety Lieutenant (jg) Cassady tirelessly and skilfully administered to the wounded in the face of hostile gunfire thereby contributing greatly to the success of this operation. His cool courage and heroic devotion to duty were a constant inspiration to his corpsmen and were in keeping with the highest traditions of the United States Naval Service. Lieutenant Cassady graduated from the University of Cincinnati College of Medicine in 1941. His home address is Cincinnati.

NEW PROCUREMENT AND ASSIGNMENT SERVICE ADDRESS

The Central Office of the Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Sanitary Engineers and Nurses in Washington, D C was moved on July 24 from 1006 U Street NW to 1778 Pennsylvania Avenue NW. Future communications should be sent to the latter address.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to the *Aftonbladet* Stockholm April 12, the quelling authorities have attempted to force Norwegian doctors to pay a compulsory yearly subscription of 100 kroner to the national socialist organization. This has encountered determined opposition, and nearly all the doctors are declaring that they will not bow to the demands of the national socialist organization or of the authorities.

Radio Paris of April 13 states that the secretary of state for health and the family has issued a reminder that under the law of March 25 1943 doctors, pharmacists and dentists established since Jan 1 1940 who have not yet joined the Order of Doctors of the Chamber of Pharmacists must register within fifteen days at the office of the health inspector of their prefecture. In principle all those who are able to follow their profession in civilian life will be considered as able to do so in prisoners camps. The stay there would last one year.

Reich Health Leader Dr Conti according to DNB, Germany April 14 stated at a conference of the Reich Midwives Association that the fall in the mortality rate of mothers had continued even during the recent war years. He thanked the midwives for these good results which they have achieved at births at which they attended unaided. This applied to 75 per cent of all childbirths which were seen through by midwives established in free practice on their own responsibility while they acted as doctors assistants in the remaining 25 per cent of childbirth cases. The reich health leader specially praised the fine efforts and the courage displayed by midwives in areas exposed to air raids for which several of them had been awarded the War Merit Cross.

According to *Universul* Rumania April 3 in view of the campaign against epidemics, Dr I Apostolescu chief municipal doctor of Bucharest has decided that the Casa Asigurarilor

Sociale should contribute two groups for delousing and disinfection. In the framework of the same campaign 50 beds have been provided in a special pavilion of the Colentina hospital for convalescents from infectious diseases.

Universul Rumania March 29 reports that in view of the fact that the present situation renders the supply of medicines containing insulin very difficult, the Ministry of Health has ordered a census of all persons suffering from diabetes and a rationing of the medicines containing insulin so that this ingredient can be economized. The census will be made by medical clinics and the services for internal medicine. The census must be finished by March 31 when insulin cards will be issued.

According to the *Petit dauphinois* France April 28 the compulsory antitetanic and antidiphtheritic vaccination of children between 1 and 14 will be carried out in Annecy before June 16. Parents who do not comply are under severe penalties.

According to *Wiesci Polska* Budapest April 2 from April 1 the so called state medical courses for students of Aryan origin or non German nationality will be opened in Lwow. Persons who have had six months labor service will be admitted. Instead of labor service sanitary work in hospitals, work in the reich or services rendered in combating the typhus epidemic may also be recognized.

In France *l'Effort* of May 19 reports that after ten years research Prof Gaston Ramon with the assistance of Drs Lemetayer, Minguet, Touze-Yen and Paul Ramon has discovered a serum against foot and mouth disease obtained from horses. The first experiments being most successful it is hoped that a large scale production will prevent the recurrence of foot and mouth disease which caused the loss of a million head of cattle in France in 1927.

Medical News

(PHYSICIANS WILL CONFIR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Dr Askey Resigns as President of School Board—Dr Edwin Vincent Askey has resigned as president of the Los Angeles City Board of Education. In his letter of resignation Dr Askey said "As long as the war continues I feel my first duty lies in the practice of medicine." Dr Askey was elected to the board for a four year term in May 1937. During the 1940-1941 school year he was president of the board and in 1941 was reelected for a second four year term.

CONNECTICUT

Mobile X-Ray Unit—The new mobile x-ray unit of the Connecticut State Tuberculosis Commission recently started its first survey of industrial groups in cooperation with the New Haven Department of Health. The work is being carried out among employees of industrial plants.

Hartford Responds to Drive for Funds—On July 9 only \$155,000 was needed in the campaign for a fund of five million dollars for the Hartford Hospital. A concentrated program was directed by Will, Folsom and Smith, Inc., New York. At a "Victory Dinner" of volunteers 147 corporations subscribed more than \$1,800,000, 410 subscriptions from individuals and families accounted for more than \$2,500,000 and 28,314 employees in industrial plants subscribed more than \$169,000. The funds are to be used to finance a building program at the Hartford Hospital.

KENTUCKY

Food Poisoning Traced to Pasteurized Milk—An outbreak of 32 cases of food poisoning in a Kentucky community of 8,000 population was traced to pasteurized milk, according to a recent report. The milk was sold by one of three large distributors, all patients being among customers of one distributor. A majority of the patients were children under 10 years of age. Illness was characterized by nausea, vomiting, prostration and, in a few cases, diarrhea. These symptoms developed in from one to seven hours after consumption of the milk. Ninety-eight cows, distributed in four herds, were examined. Investigation at the pasteurizing plant revealed insanitary conditions. Probably the most important observation was that afternoon milk, after being run over the cooler into the pasteurization vat, was allowed to stand without further cooling until about 9 o'clock the following morning. There was evidence that the milk temperature during the night rose as high as 76 F. In a report, Dr Fred W. Caudill, Louisville, director of the division of communicable diseases of the Kentucky State Department of Health, and Melvin A. Meyer, state milk sanitarian, concluded that the outbreak was due to staphylococcus toxin developed during the several hours of pasteurization when the milk was at about room temperature.

LOUISIANA

Stamp Collection Given to Tulane—Dr B. Bernard Weinstein, instructor in gross anatomy and gynecology at Tulane, has presented a postage stamp collection to the Tulane University of Louisiana School of Medicine, New Orleans. According to the *Tulanean* the collection contains stamps honoring such characters of medical history as Imhotep, an Egyptian deity of medicine, and the Curies, discoverers of radium. The collection is said to be one of the largest in the country. Dr Weinstein graduated at Tulane in 1937.

Dr Erwin Nelson Joins Burroughs Wellcome & Company—Dr Erwin E. Nelson, since 1937 professor and head of the department of pharmacology at Tulane University School of Medicine, New Orleans, has been appointed director of research of the Burroughs Wellcome & Company (United States) experimental research laboratories at Tuckahoe, N. Y. Dr Nelson had received his Ph.D. at the University of Missouri, Columbia, in 1920 and graduated at the University of Michigan Medical School, Ann Arbor, in 1926. He had been assistant

professor in pharmacology at Michigan from 1919 to 1927, associate professor from 1927 to 1936 and professor from 1936 to 1937, when he joined the Tulane faculty. Among other positions held during his career Dr Nelson was principal pharmacologist and chief of the division of pharmacology of the Food and Drug Administration for a year in 1935. He has been consulting pharmacologist to the administration since 1936. He is an Associate Fellow of the American Medical Association and in 1939 was chairman of its Section on Pharmacology and Therapeutics.

MASSACHUSETTS

State Medical Election—Dr Elmer S. Bagnall, Groveland, was chosen president-elect of the Massachusetts Medical Society at its annual meeting in May and Dr Roger I. Lee, Boston, was installed as president. Dr Michael A. Tighe, Boston, is the secretary.

Personal—Brenton R. Lutz, Ph.D., professor of biology in the Boston University College of Liberal Arts, has been elected a fellow in the American Academy of Arts and Sciences. Dr Frank H. Lahey, Boston, recently received the degree of doctor of science from Boston University.

Creation of Nutrition Chair Marks Seventieth Birthday of Frances Stern—On July 4 Miss Frances Stern, chief of the food clinic of the Boston Dispensary, Boston, observed her seventieth birthday. To commemorate this event a fund has been established in the Tufts College Medical School to be used by her to extend the research and educational activities of the clinic. A department of nutrition will be set up and staffed by selected members of the faculty for the duration of the war with the hope that later a full professor of nutrition may be installed. The food clinic at the dispensary has been named the Frances Stern Food Clinic to honor further the woman who established it twenty-five years ago. The clinic is said to be the first of its kind and was established in 1918. After her return from Paris, where she had been head worker of *Pour l'Enfance et la Famille par l'Aide Sociale*, which had been carrying on the service begun by the American Red Cross, the food clinic became the main concern of Miss Stern. The plans in her honor are being carried on by the Frances Stern Seventieth Birthday Fund begun by many of her friends. Judge A. K. Cohen, president of the Jewish Philanthropies, is chairman. In 1908 Miss Stern was assistant to Mrs. Ellen H. Richards, first woman student and teacher at the Massachusetts Institute of Technology and founder of the American Institute of Home Economics.

MINNESOTA

Changes at the University of Minnesota—Dr J. Charnley McKinley, head of the department of medicine and director of the division of nervous and mental diseases, University of Minnesota Medical School, Minneapolis, has been named head of the newly established department of neuropsychiatry at the school, which includes the division of adult psychiatry and child psychiatry. Dr Cecil J. Watson has been named head of the department of medicine and director of the division of internal medicine. Dr Raymond N. Bieter, professor of pharmacology, has been appointed head of the department of pharmacology to succeed the late Dr Arthur D. Hirschfelder. According to an announcement, recent promotions at the university include:

Harold A. Whittaker, B.A., to clinical professor of preventive medicine and public health.
Dr Ralph T. Knight to clinical professor of anesthesia.
Dr Wallace D. Armstrong to professor of physiologic chemistry.
Dr Clarence D. Dennis to associate professor of surgery.
Dr N. Logan Leven to clinical associate professor of surgery.
Dr Charles E. McEwen to associate professor of obstetrics and gynecology.
Dr Charles E. Connor to clinical associate professor of ophthalmology and otolaryngology.
Joseph T. Cohen, D.D.S., to clinical associate professor of pediatrics.
Miss Ruth B. Freeman to associate professor of preventive medicine and public health.
George O. Pierce, M.S., to associate professor of preventive medicine and public health.
Dr Edward A. Regnier to clinical associate professor of surgery.
Dr Thomas J. Kinsella to clinical associate professor of surgery.
Dr Frank W. Whittemore to clinical associate professor of neuropsychiatry.
Dr Frederick W. Hoffbauer to assistant professor of medicine.
Dr Thomas Lowry to clinical assistant professor of medicine.
Dr Alphonse E. Walsh to clinical assistant professor of medicine.
Dr James K. Anderson to clinical assistant professor of surgery.
Dr Willard D. White to clinical assistant professor of surgery.
Dr Hewitt B. Hannah to clinical assistant professor of neuropsychiatry.

MISSISSIPPI

New Assistant Dean at University of Mississippi—Dr James B. Looper, professor of anatomy at Mississippi has been appointed assistant dean of the University of Mississippi School of Medicine University.

State Medical Election—Dr Benjamin L. Crawford, Tylertown, was chosen president elect of the Mississippi State Medical Association at its annual meeting, May 12 and Dr Ellis LeRoy Wilkins, Clarksdale, was installed as president. Dr Thomas M. Dye, Clarksdale, is the secretary. The 1944 meeting will be held in Jackson, May 9-10.

MISSOURI

Personal—Dr Herbert S. Breytogle, a fellow in legal medicine at Harvard Medical School Boston has been appointed instructor in pathology at the Washington University School of Medicine and pathologist to the St. Louis City Hospital. He will serve also as pathologist to the coroner of St. Louis County.

State Medical Election—Dr Curtis H. Lohr, St. Louis, was chosen president elect of the Missouri State Medical Association at its recent annual meeting and Dr Andrew W. McAlester, Jr., Kansas City, was installed as president. Dr Ralph L. Thompson, St. Louis, is the secretary-editor. The 1944 meeting is planned for Kansas City.

Dr Muench Released—Newspapers report that Dr Ludwig O. Muench, St. Louis, was released on June 6 from the federal prison at Terre Haute, Ind., after serving six years on a conviction of using the mails to defraud. In 1935 Dr Muench was found guilty of unlawfully and fraudulently making out signing and certifying a fraudulent birth certificate. In 1936 he was charged by indictments in nine counts with wilfully, knowingly, unlawfully and feloniously using and causing to be used the United States mails to defraud and obtaining money and property by means of false and fraudulent pretenses. In 1937 his license to practice medicine was revoked by the state board of health for unprofessional and dishonorable conduct.

NEW JERSEY

Dr Leverett Bristol Named State Health Director—Dr Leverett D. Bristol, Montclair, health director of the American Telephone and Telegraph Company since 1929 has been appointed health director of New Jersey for a four year term. If he accepts, Dr Bristol will succeed Dr Jesse Lynn Mahaffey, Camden, who has held the office for the past twelve years. Dr Bristol was born in Chicago in 1880 and graduated at Johns Hopkins University School of Medicine, Baltimore, in 1907. After practicing medicine in St. Paul, Dr Bristol went to the Syracuse (N. Y.) University College of Medicine in 1913 as associate professor of bacteriology. From 1914 to 1916 he was professor of bacteriology at the University of North Dakota School of Medicine, Grand Forks, and director of the laboratories of the state health department. For a year in 1916 he was a member of the faculty of Harvard Medical School, Boston. He served as state commissioner of health of Maine from 1917 to 1921 and professor of preventive medicine and public health at the University of Minnesota Medical School, Minneapolis, for a year in 1922. He was director of the New York State Health Demonstrations from 1923 to 1929 when he became health director of the American Telephone and Telegraph Company. He is a member of the Council on Industrial Health of the American Medical Association. Dr Bristol is a member of a number of health groups and at one time served as president of the New Jersey Health and Sanitary Association and the Montclair Council of Social Agencies.

NEW YORK

Outbreak of Sore Throat Among Hospital Employees—An outbreak of 23 cases of sore throat, most of them quite severe, among interns and employees of a hospital in the upstate area was recently reported to the state department of health. The illnesses were thought to be from a common source since all the persons involved ate in the hospital dining rooms. There were no attacks among the patients and only one among the group of 255 nurses who ate their meals in separate rooms. Of particular importance was the observation that with the exception of one person, all those affected drank large quantities of milk daily. This person did not drink milk during the week of the outbreak but did occasionally drink milk and use cream in coffee and on various foods. A survey of the milk handling procedure in the hospital disclosed certain inadequacies especially in the washing of milk containers. Laboratory

study disclosed that in all of 10 cases the individuals were carrying hemolytic streptococci in their throats, and a throat culture of the hospital milk handler also proved positive. According to *Health News*, it is believed that the outbreak was due to contamination of a portion of the milk.

New York City

Promotions at Cornell—Dr McKen Cattell, associate professor of pharmacology in charge of the department, Cornell University Medical College, has been promoted to professor of pharmacology and head of the department. Dr John M. McLean has been promoted to professor of clinical surgery (ophthalmology).

Coordinating Committee for Nutrition Work—Grace MacLeod, Ph.D., has been named in charge of a special planning committee to carry out the city nutrition program originally set up by the department of health to disseminate information in the best use of the available food supply in terms of a well balanced diet. The special planning group will be part of the coordinating committee sponsoring the program.

Academy of Medicine Receives Endowments—The New York Academy of Medicine recently announced the establishment of two new funds to assist in the support of its educational projects. One the George R. Siedenbush Memorial Fund was established to defray expenses in connection with lectures given at the academy. The second is an endowment in perpetuity of the Graduate Fortnight and was created by R. Thornton Wilson as a memorial to his wife Frances Elizabeth Wilson.

OHIO

Pharmacy Dean Joins Winthrop Company—Edward D. Davy, dean of the School of Pharmacy, Western Reserve University, Cleveland, has been appointed director of the pharmaceutical division of Winthrop Chemical Company with headquarters in Rensselaer, N. Y. Mr. Davy has been associated with Western Reserve for twenty-one years, serving first as professor of pharmaceutical chemistry and becoming in 1940 dean of the school of pharmacy. From 1930 to 1940 he served on the Committee of Revision, U. S. Pharmacopeia.

Physician Honored—A portrait of Dr. Elizabeth Campbell was recently unveiled in Christ Hospital, Cincinnati, in recognition of her forty-one years service as a member of the staff. Dr. Campbell in 1909 organized the Cincinnati Visiting Nurse Association. In 1917 the Cincinnati Social Hygiene Society serving as its first president and in 1932 the Cincinnati Committee on Maternal Health. In 1942 Dr. Campbell was given an honorary life membership in the American Social Hygiene Association having served as a member of its board from 1925 to 1936 and from then until 1938 as vice president.

Promotions at Western Reserve—John Paul Quigley, Ph.D., associate professor of physiology at Western Reserve University School of Medicine, Cleveland, has been named professor of gastrointestinal physiology and Edward Muntwyler, Ph.D., associate professor of biochemistry, professor of experimental biochemistry. Dr. Quigley, who received his Ph.D. at the University of Chicago in 1929, has been a member of the staff of Western Reserve since 1929. He had previously served at the University of Georgia, Augusta University of Alberta, Edmonton and the University of Chicago. Dr. Muntwyler received his Ph.D. at the State University of Iowa, Iowa City, in 1928, joining Western Reserve in the same year. He had been an assistant in biochemistry at Iowa from 1924 to 1927.

TEXAS

Southwestern Medical Foundation School of Medicine—The registration of students on June 21 marked the official opening of the Southwestern Medical Foundation School of Medicine, Dallas. The medical school originated through the Southwestern Medical Foundation which under its charter was authorized to carry on medical education and research. The new school is housed temporarily in the Alex. Spence Junior High School, the accommodations to be available until September 1. After this period the school of medicine will be quartered in temporary wooden buildings for the duration of the war. Dr. Donald H. Slaughter is acting dean of the medical school and professor of pharmacology and chairman of the department. Dr. Edward H. Carr is the president. The faculty is composed of a large number of teachers formerly on the staff of Baylor University School of Medicine now removed to Houston. The Southwestern Medical Center will ultimately occupy 25 acres of land but the Parkland Hospital and Hines Boulevard purchased in 1942 by the foundation.

This site augments the 11 acres occupied by Parkland Hospital. This year trustees of the foundation invited the citizens of Dallas to provide an initial \$1,500,000 to launch the new school. The directors of the Dallas Chamber of Commerce and Citizen's Council endorsed the project and pledged a fund of \$100,000 annually for not less than ten years toward the operation of the school and medical center. The Southwestern Medical Center plans eventually to have at least ten million dollars in buildings and the goal for its endowment has been set for fifteen million dollars.

VERMONT

Dr Goodman Named Professor of Pharmacology at Vermont—Dr Louis S Goodman, assistant professor of pharmacology, Yale University School of Medicine, New Haven, Conn., has been appointed professor of pharmacology and physiology and chairman of the department at the University of Vermont College of Medicine, Burlington. Dr Goodman graduated at the University of Oregon Medical School, Portland in 1932 and has been a member of the staff at Yale since 1935.

GENERAL

Board Examinations—Oral examinations including the subspecialties will be given by the American Board of Internal Medicine in New Orleans on August 10 and 11. The schedule is full for this examination. The oral examination including subspecialties will be held in San Francisco on September 16-18. Applications must be filed on or before August 15.

Diploma Lost—Dr Arthur A Marmor, Denver reports that his diploma issued to him in June 1942 by the University of Colorado School of Medicine has been lost. According to Dr Marmor the diploma was inside a suitcase which was stored in a room at the U S Marine Hospital, Norfolk, Va. The suitcase was stolen sometime during the year ended July 1943.

Otorhinologic Society—On May 27 the American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery was incorporated. The society was organized on Oct 17, 1942 to create a body of qualified physicians who are specialists in otorhinolaryngology and who have training and experience in plastic and reconstructive surgery. Officers of the group are Drs Romeo A Luongo, Philadelphia, president, Morris S Bender, New York, vice president, Jacob Daley, New York, secretary, and Nathan Settler, New York, treasurer.

Brochure on Roentgenology of the Heart—The Medical Department of the Equitable Life Assurance Society of the United States recently prepared an educational brochure on Roentgenology of the Heart. This is being distributed on request without charge to members of the medical profession by the Picker X-Ray Corporation, 300 Fourth Avenue, New York. The booklet serves as a complete atlas for the subject, carrying illustrative charts and text. The object of this brochure is to review some of the methods for determining the heart size and to indicate the sphere of usefulness of roentgen examination in various types of heart disease. Certain phases which are not discussed in detail, such as fluoroscopic and kymographic study of the cardiac pulsations, and contrast visualization of the heart chambers, are referred to in an appended reading list.

New Industrial Hygiene Officers—The National Conference of Governmental Industrial Hygienists at its meeting in Rochester, N Y, May 24-27, elected Dr Paul A Brehm, Madison, Wis., chairman, Manfred Bowditch, Boston, vice chairman, and J J Bloomfield, Washington, D C, secretary-treasurer. Officers of the American Industrial Hygiene Association chosen for the coming year include Helmuth H Schrenk, Ph D, Pittsburgh, president, Mr Bloomfield, president-elect, Edgar C Barnes, Pittsburgh, secretary, and John B Littlefield, Pittsburgh, treasurer. The American Association of Industrial Physicians and Surgeons chose the following officers: Drs Harvey Bartle, Philadelphia, president, Frederick W Slobe, Chicago, president-elect, Melvin N Newquist, New York, and Loyal A Shoudy, Bethlehem, Pa, vice presidents, and Edward C Holmblad, Chicago, treasurer and managing director. The officers of the three groups were selected at the first joint meeting on May 24.

Special Society Elections—At an election of officers of the American Board of Neurological Surgery, May 6, Dr Howard C Naffziger, San Francisco, was chosen chairman, Dr Max M Peet, Ann Arbor, Mich, vice chairman and Dr Paul C Bucy, Chicago, secretary-treasurer. Dr Alexander R Stevens, New York, was chosen president-elect of the American

Association of Genito-Urinary Surgeons in June and Dr Benjamin S Barringer, New York, was installed as president. Dr Charles C Higgins, Cleveland, is the secretary. At the annual meeting of the American Ophthalmological Society in June Dr S Judd Beach, Portland, Maine, was chosen president-elect and Dr John Green, St Louis, was installed as president. Dr Walter S Atkinson, Watertown, N Y, is the secretary. The next annual session will be held in Hot Springs, Va, May 29-31. Dr Alice Woolley, Poughkeepsie, N Y, was chosen president-elect of the American Medical Women's Association at its annual meeting in June and Dr Zoe A Johnston, Pittsburgh, is the secretary. Officers of the Society of American Bacteriologists are Rebecca C Lancefield, Ph D, New York, president, Ira L Baldwin, Ph D, Edgewood Arsenal, Md, vice president, and William C Frazier, Ph D, Madison, Wis, secretary-treasurer.

LATIN AMERICA

Blood Banks in Brazil—A blood bank was recently established in Rio de Janeiro. Another one is being organized in Fortaleza, Ceara.

Pan American Ophthalmologic Congress Postponed—Announcement is made of the postponement of the Pan American Congress of Ophthalmology, which was scheduled to be held in November in Montevideo.

Courses on War Surgery—Courses on war surgery were opened recently at the Instituto Benjamin Baptista, rua Frei Vaneca, 94, Rio de Janeiro, by the Syndicate of Surgeons of Rio de Janeiro, under the auspices of the Department of Health of the National Army.

Aztec Medal to Americans—The medal of the Aztec Eagle for services and work on military medicine was recently awarded in Washington, D C, to Drs Edgar Erskine Hume and Tomas Cayigas, Washington, D C, honorary members of the Academia Nacional de Medicina of Mexico. Dr Francisco Castilla Najera, the ambassador of Mexico in the United States, presented the medals to Dr Hume and Dr Cayigas.

Centennial Anniversary of Chair of Legal Medicine—Ceremonies were recently held in the Faculty of Medicine of the University of Havana in celebration of both the one hundredth anniversary of the establishment of the chair of legal medicine and toxicology of the faculty and the twenty fifth anniversary of Dr Ramundo de Castro y Bachiller as regular professor of the chair. A feature of the celebration was the unveiling of a plaque dedicated to Dr de Castro y Bachiller by the members of the chair and of the museum of legal medicine and by the pupils and friends of Dr de Castro.

FOREIGN

Wellcome Museum of Medical Science and Historical Medical Museum—In answer to many inquiries, an announcement has been issued concerning the Wellcome Museum of Medical Science and the Wellcome Historical Medical Museum. They are and will continue to be housed in the Wellcome Research Institution, 183-193 Euston Road, London, N W 1. Although the Wellcome Research Institution building suffered considerable damage by enemy action, its structure was unharmed and the museums can quickly be put into shape again as soon as labor and materials become available after the war.

Vitamins in Northern Russia—Scurvy has been eliminated in Kolyma, one of the northernmost districts of the Union of Socialist Soviet Republics, through the use of antiscorbutic preparations which are produced of local raw materials in a factory there. According to the *Information Bulletin* of the Embassy of the Soviet Union, vitamin C is extracted from the stunted cedar and syrups, and jams with a high vitamin content are manufactured from the northern wild rose and various berries which grow abundantly in the valleys of rivers flowing through the taiga. The factory furnishes surrounding districts with the products. Thousands of liters of juices and wines are also produced.

CORRECTION

Dr Reifenstein's Name Omitted from Cardiology List—In announcing the program of Wartime Graduate Medical Meetings arranged by Syracuse University College of Medicine in *THE JOURNAL* June 26 page 608, the name of Dr I C Reifenstein, professor of medicine was erroneously omitted from the list of teachers in connection with the course in cardiology.

LONDON

(From Our Regular Correspondent)

June 19, 1943

Consultant Criticism of the Government's Proposals for a State Medical Service

In the House of Lords the government scheme for a state medical service was severely criticized. Lord Derwent said that an ancient and honorable profession would be degraded from its high calling and thwarted in its best efforts to improve itself if it was turned into a band of salaried functionaries. Further the ordinary citizen would lose by being put into the hands of an indifferent and perhaps tired and harassed functionary on a local government body. Two leading consultants followed. Viscount Dawson of Penn (consulting physician to the London Hospital) said that the government had introduced a spirit of haste and hustle instead of proceeding gradually. It would be disastrous if doctors were to be regarded as agents to control monetary benefits in the interests of the social security fund. We should not pull up the existing system by the roots until we were sure we had something good to replace it. Freedom for initiative and individual responsibility were the life blood of the medical profession who could ill fit into a bureaucratic machine. The only chance of the acceptance of the local authority as the ultimate administrative agent was to have at the elbow of each area authority an advisory council consisting of representatives of the government hospitals and the voluntary hospitals with a considerable proportion of physicians. The medical profession would not consent to be pawns on the local government chessboard; they would not consent to the government of a highly skilled profession by laymen. Lord Moran (president of the Royal College of Physicians) said that it was essential that all the activities concerned with health should come under one department and not under six as at present. He had in mind a medical council which should consider policy with the minister of health, would meet regularly and publish uncensored reports. A second essential was that the conditions under which the rank and file of the profession worked must be made as perfect as possible. If doctors combined eight or nine together, and saw patients in a house built for the purpose and suitable for diagnosis, with a consultative service at their elbow, they would breathe again the atmosphere of their student days and this would be a great gain to the community. It would be quite useless to try to drag them to work under local authorities unless assurances were given that there would be no interference with the working of their profession. The personal relation between doctor and patient would be imperiled if some of the arrangements suggested were carried out. A good consultative service was essential, and at the present time there were not enough consultants and those available were not distributed according to the needs of the community.

Replying for the government Lord Snell said that any proposal would be carefully examined and no hasty decision would be taken. It was not his experience that doctors were reluctant to become servants of a local authority. The government had made no final decisions about the suggestion that the medical profession might be turned into a state salaried service. A free choice of doctor was desirable wherever that was possible but he was not among those ultraloyal souls who would prefer to be under the care of a doctor whom he knew rather than be cured by a perfect stranger. The government was resolved that while there should be no irresponsible haste there would also be no unnecessary delay.

Eve's Rocking Method of Artificial Respiration

In 1932 Dr F C Eve of Hull, England, described a new method of artificial respiration which, unlike all previous methods, works by the force of gravity. It has been adopted on our warships as the method of choice. Our naval surgeons found Schater's method—the one in vogue—seldom successful. Eve points out that Schater based it on experiments on the normal subject on whom it works well and his claim holds that when the pressure on the chest is relaxed the same volume of air as that expelled must pass in again. But in cases of drowning—the principal contingency for which artificial respiration is used—the inspiratory recoil may be lost. The lack of elasticity is due to loss of tone in the diaphragm which has become flaccid. In some countries Sylvester's method is preferred because the bony thorax has some resilience apart from muscle tone. Schater's method relies on tone, Eve's method is independent of tone.

In Eve's method the victim of drowning is laid face downward on a stretcher and is well wrapped with blankets above and below. His wrists and ankles are lashed to the handles. Then he is hoisted on a trestle or sling and rocking is begun. The first tilt should be head down and steep (50 degrees) and should produce full expiration by the weight of the abdominal contents pressing on the diaphragm. It will also force aortic blood through the coronaries and empty the stomach and lungs of water. Then full inspiration is produced by tilting the foot end down to 50 degrees. The rocking is done a dozen times a minute through an angle of 45 degrees each way. The method is safe and can be done by anybody. During any delay in getting the stretcher it is recommended that Schater's method be used until the rocking can be started.

Great Deterioration in German Vital Statistics

The *Times* states that recently published statistics of mortality in German cities show a steadily deteriorating health of the urban dweller especially in the later months of 1942. The following German official figures refer only to the large cities of Greater Germany with a total population of 24,500,000. Compared with the corresponding months of 1941 infant mortality rose by 17 per cent during the last quarter of 1942 to 69 per thousand live births. For the whole year the rate was 66 against 59 for 1941. This contrasts with a record low rate of England and Wales of 49 during 1942. Among children aged 1 to 5 years—another sensitive index of health—the number of deaths rose sharply in 1942 to 7,236. In previous years the numbers had been 6,404 in 1941, 6,062 in 1940 and 5,670 in 1939. Thus the number of deaths has steadily increased during the war. School children aged 5 to 14 also show a similar increase, but adolescents seem to be more affected than any other group. For ages 15 to 20 the mortality showed a rise of 38 per cent compared to 1939. The numbers were 4,159 in 1942, 3,192 in 1941, 3,126 in 1940 and 3,023 in 1939. Contributing to these significant upward trends in children's mortality were sharp increases in the number of deaths from diphtheria and scarlet fever. The deaths from tuberculosis showed a sharp rise. From all forms there were in the German cities nearly 5,500 more deaths in 1942 than in 1939. The death rate per thousand at all ages was 24 per cent higher in 1942 than in 1939 and the rise was more rapid in 1942 than in 1941.

A Lower Birth Rate

The latest figures show a dramatic fall in the birth rate. For the large German cities the number of births in 1942 declined by 80,000 from the figure of 419,000 in 1940 and the rate per thousand of population fell to 13.9 compared with 17.3 in 1940. In the last quarter of 1942 the rate was as low as 12.7. The experience of the German cities is borne out by the rate for all areas of Greater Germany which declined from 20.4 in 1939-1940 to 15.2 in 1942, a loss of 25 per cent over 550,000 live births.

AUSTRALIA

(From Our Regular Correspondent)

June 15, 1943

Parliamentary Joint Committee on Social Security

The Parliamentary Joint Committee on Social Security was appointed "to enquire into and from time to time report upon ways and means of improving social and living conditions of the people of Australia and of rectifying anomalies in existing legislation." During the past few months the committee has been taking evidence from members of the medical profession in the different states on the question of nationalization of medical and ancillary services. The questionnaire submitted to witnesses is a basis for the presentation of evidence took this form:

1 What is your conception of the medical, hospital and health services required by the people of Australia, and how and under what conditions do you consider such services should be provided?

2 Are you familiar with, and which, if any, of the following do you consider suitable for application in Australia: (a) the proposal of the National Health and Medical Research Council for a salaried medical service, (b) the proposal of the federal council of the British Medical Association in Australia for a general medical service in Australia, (c) medical, hospital and related benefits as in operation in New Zealand, (d) national health insurance?

3 Do you consider any of the following services could and/or should be introduced during the war? (a) the whole or any portion of any such scheme as you favor, (b) any other medical, health, hospital or welfare service or benefits, or alternatively (c) that any financial provision should be made for services or capital expenditure after the war, (d) if your answer to the foregoing is in the affirmative, can you give details?

4 Have you any proposals regarding the following which you would like to submit and which might be included in a comprehensive health scheme or as an instalment of it: (a) child welfare, (b) maternal welfare, (c) tuberculosis, (d) hospital benefit scheme, (e) hospital accommodation and organization, (f) group practice, (g) national fitness, (h) any other health service or benefits, and which of these, if any, do you consider should be introduced during the war? after the war?

5 Have you any suggestions as to the means that should be adopted to secure the introduction and efficient administration of a comprehensive health scheme in Australia, or any part of such scheme, and the cooperation of all interested parties?

The committee has more than once insisted to witnesses that it has no preconceived plan and that it intends to sift available evidence in a search for the most suitable scheme of medical services for Australia.

Problems of War Neurosis

The effects of war neuroses and problems arising in the rehabilitation of discharged soldiers are discussed in a report prepared by the Society of Returned Medical Officers of Queensland, of which Dr Jarvis Nye is president. The report states that the biggest readjustment the discharged soldier has to make is that of resuming personal responsibility for his own livelihood. Men should be discharged from the army as soon as it becomes evident that they will not again become efficient soldiers. The disabled soldier should be trained to an occupation at the earliest possible moment, and the maximum of training time should be spent on useful and gainful work. With regard to pensions, the report states "We wish it to be clearly understood that we consider that the commonwealth is under definite obligation to give adequate pensions, but we definitely

deplore the psychological handicap which a pension bestows on any soldier, who, by grit and determination, could have avoided it." In many cases the mere granting of a pension is shelving official responsibility. Far more attention should be given to rehabilitation. The Repatriation Commission, with its years of experience, is the logical body to deal with the problem of the serviceman. The rebuilding of social background is considered of major importance for the success of any plan for repatriation and rehabilitation.

Services Medical Merger Planned

There is an acute shortage of hospital staffs for the civilian population in Australia. Hospitals in all the states are forced to keep large numbers of beds unoccupied because of the inadequacy of their nursing, domestic and laundry staffs. Unless the situation is relieved, many metropolitan and country private hospitals will soon be forced to close down.

It has been suggested that considerable manpower could be made available for the civilian population by merging the medical and nursing personnel of the services into one combined service. Under the present system there are in many towns separate hospitals for the army and the air force, and this entails much unnecessary duplication of the work of the services' medical and nursing personnel.

The director general of manpower (Mr W C Wurth) has discussed a scheme for a unified medical and nursing service with the navy, army and air force authorities, who have agreed to investigate its possibilities and to inform him of their views as soon as possible. One direct effect of the scheme will be a reduction in any further intake of nurses for the fighting services.

Invitations to American Medical Officers

Invitations have been extended to medical officers of the armed services of the United States to attend all scientific meetings of the Australian branches of the British Medical Association. In Queensland they have been offered various other facilities including the use of the branch library and have been invited to attend postgraduate courses arranged by the Queensland Postgraduate Committee. During a weekend course held recently in Brisbane several American medical officers took part as lecturers in the program. Arrangements have also been made for the regular supply of copies of the *Medical Journal of Australia* to each medical unit of the United States Army in Australia.

Marriages

ERLOND H HEDRICK to Miss Myrtle Adele Wade, both of Berkeley, W Va., in Baltimore, June 23

J HARRY DUNCAN, Hazlehurst, Ga., to Miss Mary Jane Martin of Union City, Tenn., in June

JOHN S STEWART, Warren, Pa., to Miss Annie M Ramwater of Florence, S C., June 19

THOMAS A HEDRICK, Baltimore, to Miss Jane Miller House at Mercersburg, Pa., June 5

JAMES BALLEW, Americus, Ga., to Miss Martha Maxine Elliott of Atlanta, June 27

ALBERT B WOLFE, Orangeburg, S C., to Miss Anna Lou Black in Bowman, June 15

THOMAS H DAVIDSON, Casper, Wyo., to Miss Elaine Carroll of Ottawa, Ill., June 21

JOHN H ABBOTT to Miss Eleanor J Gilmore, both of Allen town, Pa., recently

JOSEPH W KRYSOSLK to Miss Josephine Lobacz, both of Chicago, July 11

JACK MASUR to Miss Barbara Forsch, both of New York, June 28

Deaths

Leslie Tillotson Webster, member of the Rockefeller Institute for Medical Research New York, died at his home in Scarsdale N Y, July 12, aged 48

Dr Webster was born in New York in 1894. He completed his studies at Amherst College in 1915 and graduated at Johns Hopkins University School of Medicine, Baltimore, in 1919. After a year as resident pathologist at the Johns Hopkins Hospital and assistant in the department of pathology at the medical school Dr Webster joined the Rockefeller Institute for Medical Research, first as assistant in the department of pathology and bacteriology and later as associate and associate member. He had been a member since July 1, 1934.

Through his work on the mechanism of the spread of disease in animal populations Dr Webster was largely responsible for the establishment of the special branch of epidemiology known as experimental epidemiology. In investigations extending over a period of fifteen years he developed by selective breeding strains of mice that manifested a ten thousand fold variation in their susceptibility to a given infectious agent. By setting up mouse populations in which the natural resistance of all the individuals was known he demonstrated that the course of an epidemic in the population was determined by the relative proportions of susceptible and resistant animals that had been introduced into the group. This work emphasized the importance of the host factor in the spread of disease, which was the theme of his De Lamar lecture in 1935.

Dr Webster had also engaged extensively in investigations of rabies and of epidemic virus diseases in man devising tests for the early diagnosis of rabies and for determining quantitatively the potency of antirabic vaccines. He developed a concentrated vaccine, containing the virus killed by ultraviolet light which gives effective protection following the injection of a single dose into animals. After the publication of his book on Rabies the Dog Writers Association voted him for 1943 its annual award for 'the person who over a long period of time has performed meritorious work in the field of dogs'. Because of his interest in encephalitis at the outbreak of the war Dr Webster was invited to participate in the work for the Commission for Neurotropic Virus Diseases of the U S Army. In this field he and his associates have made significant contributions to the specific etiology and diagnosis of the various types of human encephalitis by improving the methods of immunologic differentiation of the infectious agents.

At the time of his death he was chairman of the National Research Council's Committee on the Maintenance of Pure Genetic Strains for use in experimental biology.

Dr Webster held membership in numerous scientific groups, including the Society for Experimental Biology and Medicine, American Society for Experimental Pathology, American Epidemiological Society, American Association of Pathologists and Bacteriologists, Society of American Bacteriologists, the Harvey Society, the American Association for the Advancement of Science and the American Public Health Association. In 1935 he received the price of 1000 francs from the Faculty of Medicine of the University of Berne, Switzerland for his research on encephalitis.

His published works covered experimental epidemiology, the spread of epidemics, poliomyelitis, encephalitis, rabies and resistance to infectious diseases.

George Thomas Palmer @ Springfield Ill Northwestern University Medical School Chicago 1898 at one time assistant director and acting chief of tuberculosis state department of public health formerly health officer at Springfield specialist certified by the American Board of Internal Medicine past president of the Sangamon County Public Health Nursing and Public Health Association member and for ten years president of the Illinois Tuberculosis Association member of the American College of Chest Physicians the Institute of Medicine of Chicago American Trudeau Society and the Union League Club of Chicago served as a director of the National Tuberculosis Association past president of Illinois State Conference of Charities and Correction president and medical director of the Palmer Sanatorium a member of the staffs of the Memorial and St. John's hospitals designated examiner for tuberculosis of the U S Veterans Bureau at one time on the editorial staff of the *Journal of the Outdoor Life* aged 68 died June 14 of cerebral hemorrhage.

Benjamin Rush McClellan @ Lima Ohio Miami Medical College Cincinnati 1884 member of the House of Delegates of the American Medical Association in 1911 1913-1914 1916-

1917, from 1919 to 1923 and from 1925 to 1941 past president of the Greene County Medical Society, vice president of the Ohio State Medical Association in 1903, president in 1906-1907 and for many years a member of various committees fellow of the American College of Surgeons member of the state medical board from 1915 to 1922 past president of the Greene County Historical Society and the Rotary Club a captain in the medical corps of the U S Army during World War I serving as chief of the surgical staff at Debarkation Hospital number 2 New York City in 1898 established the McClellan Hospital, where he had been surgeon and chief of staff dean of the medical and surgical staff of the Ohio Soldiers and Sailors Orphan Home aged 83 died, June 5, in Williamsburg, Va of coronary arteriosclerotic heart disease.

Arthur Eggleston Davis @ Scranton Pa Medico-Chirurgical College of Philadelphia 1911, fellow of the American College of Physicians formerly vice president of the Medical Society of the State of Pennsylvania past president of the Lackawanna County Medical Society at one time director of public health of Scranton served in the medical corps of the U S Army during World War I on the staffs of the Scranton State Hospital and the West Side Hospital consultant in cardiology at Farview (Pa) State Hospital and the Mercy Hospital aged 56 died May 2, of coronary heart disease.

George Herbert Allen @ Newark N J New York Homeopathic Medical College and Flower Hospital, New York, 1910 on the staff of the East Orange General Hospital where he died May 6 of chronic myocarditis aged 57.

John H Andrews Buffalo Medical College of Ohio Cincinnati 1883 aged 86 died April 12 of arteriosclerosis and chronic myocarditis.

Seth Fenelon Arnold, Boston Tufts College Medical School Boston 1908 for five terms a member of the city council formerly a member of the state house of representatives served in the U S Navy during World War I aged 64 died May 9 of a self-inflicted bullet wound.

Herbert Atkins @ Pratt Kan University Medical College of Kansas City Mo 1910 past president of the Pratt County Medical Society formerly county health officer councilor of the Eleventh District of the Kansas Medical Society served during World War I aged 62 died April 10 of coronary thrombosis.

Samuel Lee Battles Washington D C George Washington University School of Medicine Washington 1906 aged 71 died May 18 of cerebral hemorrhage.

John Irving Beattie @ San Jose Calif Cooper Medical College San Francisco 1905 served during World War I president of the Santa Clara County Medical Society aged 59 on the staff of the San Jose Hospital where he died May 7, of cerebral hemorrhage.

Ralph Linwood Benjamin @ St Anne Ill Rush Medical College Chicago 1902 vice president of the American Association for the Study of Gout aged 64 chairman of the surgical section of St Mary's Hospital Kankakee where he died May 10 of injuries received when his automobile was struck by a train.

Charles C Berlin @ Wapakoneta Ohio Medical College of Ohio Cincinnati 1898 for many years secretary of the Auglaize County Medical Society director of the Peoples National Bank president of the library board a former member of the board of education aged 71 died May 3 of acute coronary disease.

William Anderson Black Asheville N C Memphis (Tenn) Hospital Medical College 1895 aged 88 died May 18 of pneumonia.

Ray Wellborn Blackmar @ Jacksonville Fla Tulane University of Louisiana School of Medicine New Orleans 1919 member of the American Urological Association aged 55 died April 21.

Robert Eugene Blake Bakersfield Calif University of California Medical School San Francisco 1933 aged 49 died May 4.

Eric Thorston William Boquist Minneapolis University of Minnesota Medical School Minneapolis 1916 served in the medical corps of the U S Navy aged 51 on the staff of the Swedish Hospital chief medical officer of the Minnesota Soldiers Home Hospital where he died April 26 of coronary occlusion.

Arthur E Broga Onondaga N Y Eclectic Medical College of the City of New York 1882, lecturer of the Medical

Society of the State of New York, served on the staff of the Oncida City Hospital, aged 90, died, April 17, of cerebral hemorrhage

Charles H. Brown, Fair Play, Mo., St. Louis University School of Medicine, 1903, member of the Missouri State Medical Association, past president of the Dallas-Hickory-Polk Counties Medical Society, for many years president of the board of education, aged 68, died, April 28, in the Springfield Baptist Hospital, Springfield, of cerebral thrombosis and arteriosclerosis

Jackson Tucker Brown, Ragland, Ala., Birmingham Medical College, 1897, member of the Medical Association of the State of Alabama, formerly local surgeon for the Southern Railway Company, aged 77, died, May 8, in a Birmingham hospital

Meritt Chesteen Brumley, Jeffersontown, Ky., University of Louisville Medical Department, 1893, aged 80, died, May 2, of nephritis

William Wiley Bryan, Hume, Miss., Memphis (Tenn.) Hospital Medical College, 1909, aged 62, died, April 24

Gulick O. Bundy, Barton, N. D., St. Louis College of Physicians and Surgeons, 1904, aged 86, on the staff of the Good Samaritan Hospital, Rugby, where he died, April 29, of carcinoma of the bladder

Benjamin Wade Burleigh, Ragan, Neb., Northwestern University Medical School, Chicago, 1905, aged 79, died, April 9, in the Holdrege (Neb.) Hospital of myocarditis

Charles Wesley Burrill, Kansas City, Mo., Chicago Medical College, 1872, an Affiliate Fellow of the American Medical Association, Civil War veteran, aged 97, died, April 28

Walter F. Carver, Albion, Ind., Fort Wayne College of Medicine, 1892, secretary of the Noble County Medical Society, in 1916 third vice president of the Indiana State Medical Association, president of the board of the town council for twenty-one years and county coroner for several terms, aged 76, died, May 11, in the McCray Memorial Hospital, Kendallville, of empyema of the gallbladder

John Augustine Casey, Bridgeport, Conn., Cornell University Medical College, New York, 1918, resident physician at the Hill Side Home for fourteen years, aged 52, on the staffs of the Bridgeport Hospital and St. Vincent's Hospital, where he died, May 8, of Laennec's cirrhosis of the liver

Lowell Newton Clyne, McLeansboro, Ill., Chicago Medical School, 1939, member of the Illinois State Medical Society, aged 32, died, May 9, at St. Genevieve, Mo., in an airplane accident

Frank Michael Condron, Philadelphia, Jefferson Medical College of Philadelphia, 1919, aged 47, died, May 8, of cerebral hemorrhage and hypertension

Warren Cox Daly, Rochester, N. Y., New York Homeopathic Medical College and Hospital, New York, 1902, member of the Medical Society of the State of New York, aged 68, on the honorary staff of the Genesee Hospital, where he died, May 2, of arteriosclerotic and hypertensive heart disease

Herman P. Daniels, Wichita, Kan., Northwestern University Medical School, Chicago, 1892, served on the staff of the Wichita Hospital, aged 74, died, May 6, of myocarditis

Sylvester James Deehan, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1902, aged 66, died, May 12, in the Memorial Hospital of heart disease

Horace William Delesdernier, Danielson, Conn., University of Vermont College of Medicine, Burlington, 1885, aged 92, died, May 8, of arteriosclerosis and prostatitis

Charles Wladimir Dubin-Alexandroff, Philadelphia, Temple University School of Medicine, Philadelphia, 1918, served in the medical corps of the U. S. Army during World War I, aged 63, died, May 2

Clarence Swan Duner, Chicago, Rush Medical College, Chicago, 1917, a member of Selective Service Board number 14, served in the U. S. Navy during World War I, on the staff of the South Shore Hospital, aged 50, died, May 28, of congestive heart disease

Angus L. Emerson, Hernando, Miss., Memphis (Tenn.) Hospital Medical College, 1893, past president of the De Soto County Medical Society, past vice president of the Mississippi State Medical Association, for many years health officer of De Soto County, member of the board of trustees of the Baptist Memorial Hospital, Memphis, Tenn., a surgeon for the Illinois Central Railroad, aged 78, died, May 9, of cerebral hemorrhage

Louis Ferber, Brooklyn, University and Bellevue Hospital Medical College, New York, 1927, assistant in medicine at the Brooklyn, Jewish and Kings County hospitals, aged 41, died, May 9, of coronary sclerosis

Oscar George Finkle, Coral Gables, Fla., Columbia University College of Physicians and Surgeons, New York, 1918, aged 55, died, May 2, of gastrointestinal hemorrhage and duodenal ulcer

Charles Marc Gilmore, Beacon, N. Y., Columbia University College of Physicians and Surgeons, New York, 1919, specialist certified by the American Board of Psychiatry and Neurology, Inc., member of the American Psychiatric Association and the Association for Research in Nervous and Mental Disease, aged 47, medical director of the Craig House, where he died, May 15, of carcinoma of the colon

Henry L. Henderson, Astoria, Ore., Eclectic Medical Institute, Cincinnati, 1882, American Medical College, St. Louis, 1888, formerly mayor of Astoria, on the staff of St. Mary's Hospital, aged 85, died, April 27, of coronary thrombosis

Samuel T. Henderson, Fort Wayne, Ind., Physio-Medical College of Indiana, Indianapolis, 1896, aged 69, drowned in St. Mary's River, May 3

George Earl Hermence, Marshalltown, Iowa, State University of Iowa College of Medicine, Iowa City, 1912, on the staffs of the Evangelical Deaconess Home and Hospital and the Thomas Mercy Hospital, aged 54, died, April 25, in Conrad of cerebral hemorrhage

Kendall James Hocker, Millville, Del., Baltimore University School of Medicine, 1898, member and past president of the Medical Society of Delaware, past president of the Sussex County Medical Society, also a druggist, formerly postmaster, served as acting assistant surgeon in the U. S. Public Health Service, consultant physician to the Milford (Del.) Memorial Hospital, aged 66, died, April 24, of heart disease

James B. Hodge, Detroit, Detroit Homeopathic College, 1906, member of the Michigan State Medical Society, served on the staff of the Grace Hospital, aged 73, died recently of a hip fracture received in a fall

Edgar Lee Hughes, Commodore, Pa., Jefferson Medical College of Philadelphia, 1909, for many years physician for the New York Central Railroad coal mining division, aged 58, died, April 8, of coronary occlusion

Charles Worley Jones, Olympia, Wash., St. Louis College of Physicians and Surgeons, 1903, fellow of the American College of Surgeons, served during World War I, on the staff of St. Peter's Hospital, at one time physician in charge of the Elma (Wash.) General Hospital, aged 63, died, April 25, in Tumwater of coronary occlusion

Rudolph G. Kellner, Seattle, College of Physicians and Surgeons, Baltimore, 1904, aged 71, died, April 19

August Kuhlmann, Melrose, Minn., University of Minnesota College of Medicine and Surgery, Minneapolis, 1905, served on the staffs of the Melrose and St. Cloud (Minn.) hospitals, for twenty-five years health officer of Melrose, aged 67, died, April 4, of bronchial asthma

Frank B. Lansdowne, Kenosha, Wis., Missouri Medical College, St. Louis, 1897, for several years served as coroner of Kenosha County, aged 67, on the staffs of the Kenosha Hospital and St. Catherine's Hospital, where he died, April 19, of carcinoma of the lung with metastases to the brain

John Joseph Mahaffey, Philadelphia, Temple University School of Medicine, Philadelphia, 1938, school inspector, aged 32, on the staffs of the Memorial Hospital, Roxborough and the Temple University Hospital, where he died, May 1, of pneumonia

Edward J. Martens, St. Louis, Marion-Sims College of Medicine, St. Louis, 1897, aged 73, died, May 6, of heart disease

Charles William Martin, Hot Springs National Park, Ark., Hospital College of Medicine, Louisville, Ky., 1905, aged 69, died, May 5, of myocarditis and cardiovascular syndrome

James O. Matthews, Clinton, N. C., University College of Medicine, Richmond, Va., 1897, member of the Medical Society of the State of North Carolina, at one time state senator, aged 75, died, May 4

Aristides John Mavromatis, Newark, Del., Columbia University College of Physicians and Surgeons, New York, 1929, aged 53, member of the staff of the Delaware Hospital, Wilmington, where he died, May 3, of coronary thrombosis

Marvin Wilson McLarty, Atlanta, Ga., Atlanta College of Physicians and Surgeons, 1909, member of the Medical Association of Georgia, aged 64, died April 27, in the Crawford W. Long Memorial Hospital of heart disease.

Davis Dennis Mehigan & Milwaukee Marquette University School of Medicine, Milwaukee, 1913, a surgeon for the city police department, served during World War I on the staffs of the Misericordia and St. Joseph's hospitals, aged 52, died April 26, in Rochester, Minn., of carcinoma.

Luther Michael & San Leandro, Calif., Medical College of Ohio Cincinnati 1884, formerly city health officer, for many years physician for the Western Pacific Railway, served on the staff of the Peralta Hospital, Oakland, aged 79, died April 25, of uremia.

Ananias D. Miller, Mount Pleasant, Pa., Eclectic Medical Institute Cincinnati 1889, formerly member of the state legislature and director of the school board on the staff of the Henry Clay Frick Memorial Hospital, aged 82, died April 23, of cerebral hemorrhage.

Georgia S. Cruickshank Motz, Buffalo University of Buffalo School of Medicine 1898, aged 69, died April 29, of coronary thrombosis and pulmonary embolism.

Charles Clinton Moyer, Pittsburgh, Jefferson Medical College of Philadelphia, 1905, aged 61, died April 28.

Richard J. Muenzner, Milwaukee Wisconsin College of Physicians and Surgeons, Milwaukee, 1900, member of the State Medical Society of Wisconsin, aged 67, on the staff of St. Joseph's Hospital, where he died, April 20, of abscess of the liver.

William Simons Overton & Binghamton, N. Y., Long Island College Hospital Brooklyn 1887, also a pharmacist, at one time owner of the Moore-Overton Hospital, formerly on the staff of the Binghamton City Hospital, aged 78, died May 17, at Sag Harbor, L. I., of coronary thrombosis.

Martin Ringwalt & Rohrerstown, Pa., Jefferson Medical College of Philadelphia 1880, aged 85, died April 1.

David G. Roy, Chicago, Hering Medical College Chicago, 1904, member of the Illinois State Medical Society, served on the staff of the Englewood Hospital, aged 74, died March 18, of heart disease.

Frank Cassius Sibley, Carmi, Ill., Beaumont Hospital Medical College St. Louis 1900, St. Louis University School of Medicine 1903, member of the House of Delegates of the American Medical Association in 1917, member of the Illinois State Medical Society, served during World War I, aged 68, died May 7, in Little Rock, Ark., of pneumonia.

John Edward Cronham Snyder & Hoboken, N. J., New York University Medical College New York, 1896, formerly a druggist, aged 67, died May 14, of heart disease.

William Sonneborn, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1890, aged 79, died May 1, in the Philadelphia General Hospital of arteriosclerosis.

Enos S. Spindel, Springfield, Ill., Eclectic Medical Institute, Cincinnati, 1899, formerly a member of the state board of health, aged 73, died May 25, in St. John's Hospital of injuries received in an automobile accident.

Maurice Stayer, Johnstown, Pa., Medico-Chirurgical College of Philadelphia, 1905, member of the Medical Society of the State of Pennsylvania, served on the staff of the Conemaugh Valley Memorial Hospital, aged 66, died May 4, of coronary thrombosis.

Franklin Pierce Stevenson, Houston, Texas, Vanderbilt University School of Medicine Nashville, Tenn., 1892, aged 73, died April 23, of cerebral hemorrhage and bronchopneumonia.

Thomas Newcomb Stone & Haverhill, Mass., Harvard Medical School Boston 1903, president of the Pentucket Medical Association 1941-1942, a captain in the medical corps of the U. S. Army during World War I, on the staffs of the Hale and Bunson hospitals, chairman of the Municipal Planning Board, served many years as school physician, aged 63, died April 21, of carcinoma of the rectum.

Joseph E. Stults, Fort Wayne, Ind., Fort Wayne College of Medicine 1886, twice elected Allen county coroner, aged 86, died May 6, in the Lutheran Hospital of chronic myocarditis and chronic nephritis.

Robert Lee Summers, Des Moines, Iowa, Southwestern University Medical College Dallas, Texas, 1910, aged 61, died April 9, in the Broadlawns Polk County Public Hospital of hypertensive cardiovascular disease.

Robert Clive Sutherland, Penns Grove, N. J., Jefferson Medical College of Philadelphia, 1916, member of the Medical Society of New Jersey, formerly on the staffs of the Salem County Memorial Hospital, Salem, aged 60, died April 23, of pulmonary edema and cerebral hemorrhage.

Ezekiel Chester Swarthout, West Salem, Wis., Bellevue Hospital Medical College, New York, 1879, aged 87, died May 10, of cerebral hemorrhage.

Isadore Bennett Swickley & Braddock, Pa., St. Louis University School of Medicine 1937, served on the staffs of the Montefiore Hospital Pittsburgh, and the Braddock Hospital, aged 33, died April 10, of hypertension and heart disease.

Horace Rowe Taylor & Whitbourne, Newfoundland, University of Buffalo School of Medicine, 1912, member of the Medical Society of the State of New York, medical officer in charge of the Markland Hospital, aged 55, died April 23, of coronary thrombosis.

Frank Martin Tukey & Bridgeport, Conn., Harvard Medical School Boston 1894, past president of the Fairfield County Medical Society, served on the staff of the Bridgeport Hospital, aged 72, died April 24, of cerebral thrombosis and arteriosclerosis.

William Alonzo Vincent, Belle Plaine, Iowa, Rush Medical College Chicago, 1881, Civil War veteran, at one time on the staff of the Rochester (Minn.) State Hospital, formerly mayor of Belle Plaine, aged 96, died April 20, of hypostatic pneumonia.

Charles M. Wanzer, Cincinnati, Medical College of Ohio, Cincinnati 1883, aged 85, died April 12, of heart disease.

Harry Whitney Wheaton, Baltimore, University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore, 1917, for many years a member of the city health department, served in France during World War I, member of the staffs of the University and South Baltimore General hospitals, aged 51, died April 24, in the Bon Secours Hospital of acute circulatory collapse following spinal anesthesia.

Lyle Gordon Young, Van Buren, Ark., Kansas City (Mo.) College of Medicine and Surgery 1925, member of the Arkansas Medical Society, draft examiner for the Crawford County Selective Service System, aged 43, died April 26, of coronary occlusion.

John S. Ziegler, Washington, D. C., University of Maryland School of Medicine Baltimore 1878, member of the Medical Society of the State of Pennsylvania, aged 84, died March 1.

DIED WHILE IN MILITARY SERVICE

Kirby Knapp Bryant & Surgeon U. S. Public Health Service Charleston, S. C., University of Virginia Department of Medicine Charlottesville 1925, medical officer in charge quarantine and relief stations, district coast guard medical officer, aged 48, died April 15, in the U. S. Naval Hospital of heart block.

David Hickman Drummond & Major M. C. U. S. Army Camp Berkeley, Texas, University of Michigan Medical School Ann Arbor 1935, appointed a first lieutenant in the medical corps of the U. S. Army in February 1940 and later promoted as a major, aged 32, died Oct. 25, 1942, of pneumonia.

Julian Hawthorne Givens, Seattle, Rush Medical College Chicago 1901, member of the Washington State Medical Association, captain medical corps, Army of the United States, aged 39, died April 22, of bilateral pulmonary embolism at Camp Swift, Texas.

Hugh Joseph McLaughlin, Caldwell, Idaho, Creighton University School of Medicine Omaha 1924, diplomate of the National Board of Medical Examiners, served on the staff of the Mercy Hospital Nampa, captain medical corps, Army of the United States, aged 43, died April 11, of bronchopneumonia, in a Pullman car en route from Caldwell to Camp Adair, Ore.

Irving Roy Rathgeb, Jr., Portland, N. Y., Jones Island College Hospital Brooklyn 1935, U. S. Army (National Guard), aged 29, died February 25, in an airplane accident near Camp Adair, Ore.

ALLOXAN

To the Editor—In the first editorial of the July 3 issue of THE JOURNAL attention is drawn to the report of Dunn, Sheehan and McLetchie of Glasgow on the specific necrosing action of alloxan, the made of mesoxalic acid, on the islet cells of the pancreas and convoluted tubules of the kidney in rabbits. We have confirmed these observations in rabbits and have observed animals which survive injections of alloxan and exhibit only transitory hyperglycemia. Dunn and his co-workers observed no survivors beyond five days.

Furthermore we have observed the effects of alloxan injected intravenously in dogs. Doses of 200 to 500 mg per kilogram are fatal in one hour to five days. Where death does not occur in a few hours there is first a hyperglycemia followed by hypoglycemia, and by the end of forty-eight hours a pronounced sustained hyperglycemia obtains. The blood nonprotein nitrogen is also definitely elevated. Doses of 50 to 150 mg per kilogram are not uniformly fatal to dogs and, if the animals survive, a sustained hyperglycemia without uremia may obtain. We have observed 5 dogs with hyperglycemia sustained for two to three weeks.

There is histologic evidence of islet cell injury, but this is not as pronounced as in rabbits. The necrosing action on the epithelium of the convoluted tubules, however, is just as extensive in the dog with high nonprotein nitrogen as it is in the rabbit. In dogs in which the nonprotein nitrogen remained normal, no degenerative changes were found in the kidneys.

Of special interest is the fact that alloxan which was injected into 3 human patients with carcinomatosis, 1 of whom presented an insulin producing islet cell carcinoma of pancreatic origin, was entirely without effect either on the sugar or on the nonprotein nitrogen levels in the blood. No subjective disturbances developed. The doses injected intravenously were 220 (islet cell carcinoma), 400 and 950 mg per kilogram of body weight. These observations in man are of significance in connection with the question raised by Dunn and his co-workers of the possible relationship of the experimental chemical diabetes of alloxan to diabetes in man.

IMMUNIZATION AGAINST TETANUS

To the Editor—I should like to sound a note of warning to physicians supervising the care of children in summer camps. Many medical blanks filled out by parents prior to the camp season contain a question as to whether the child has been immunized against tetanus. If it hasn't, attempts often are made to do so before the child leaves for camp. If so, it should be remembered that, even if the full number of recommended injections are given, the interval between them is not likely to be as satisfactory as if there were more time. What is more important, however, is the fact that the antitoxin titer probably will not have reached its maximum until after the summer is over, since it has been shown that it requires about four to five months to secure the full antigenic effect of the toxoid. If the child is injured during the summer and there is a possibility of tetanus contamination, it is essential that the physician in charge find out whether the patient had previously been given adequate immunization. If it had, then a stimulat-

ing dose of tetanus toxoid should be given at the time of the injury. If, however, the child had been only partially immunized or given the injections just before going to camp, a protective dose of tetanus antitoxin should be administered except in the uncommon instances in which the patient is sensitive to horse serum. In the latter instance spaced injections combined with epinephrine may be used or bovine tetanus antitoxin given.

While active immunization against tetanus is of definite value, further data, as no doubt will be accumulated at the end of the present war, will make it possible for us to decide whether we can rely on it solely for patients with wounds possibly contaminated by tetanus organisms. Until then and whenever in doubt or for patients with badly lacerated or contaminated wounds, it is better to give the protective dose of antitoxin anyhow rather than take a chance on the active immunity engendered by the toxoid injections.

LOUIS TUFT, M.D., Philadelphia

HOSPITALIZATION FOR THE ALCOHOLIC

To the Editor—Your readers will be glad to hear that the American Hospital Association has accepted a grant from the Research Council on Problems of Alcohol, a subsidiary of the American Association for the Advancement of Science, and has appointed a subcommittee of its Council on Professional Practice to study the problem of hospitalization and to make recommendations. The help of clinicians who have given thought to this problem will be very welcome.

We have no cause for pride in this neglected field. Our hospitals are, indeed, organized in such an exclusive way that it would almost seem as if they had appointed themselves the representatives of the moral extremists in closing their doors to this peculiarly baffling malady. Every kind of patient has been provided for, in one type of hospital or other, including the patient with leprosy, whose traditional position in society as an outcast has not influenced our planning for his care. The patient suffering from primary alcoholism is left out in the cold (and pneumonia is the worst complication that can come to him, besides serious injury, even to this day) unless he is a man of wealth, in which case he can obtain private care of a palliative sort. If he is poor he is doubly cursed and, for his pains, he gets kicked around by those who, in their hearts, know better. As an urgent case he will get sobering-up treatment in an acute general hospital which does not, however, look deeper when duration of illness complicates the application for admission. We must not lull ourselves into believing that we can dispose of the problem by pleading that we have other work to do for those whom we consider more deserving. The fact is that we have gotten nowhere by stigmatizing and excluding the alcoholic patient. The committee is starting work with the conviction that this kind of patient needs our sympathetic care like all other patients for whom, because of urgency or because of any other reason, we hold our doors and our arms open.

Many hospitals which, because of the war, have been compelled to lower their personnel standards are now employing workers with a history of chronic alcoholism while trying the flattering unctious to their souls that they are making a virtue of necessity. As they engage in this enforced task of rehabilitation they are learning, from direct experience, the implications of this malady. We shall find, when peace returns to our troubled world, that it is not always necessary to take the bad with the good in civilization, and that scientific inventions and discoveries which have been put to perverted use can be controlled. So shall we find with the challenge of alcoholism. There must be a scientific solution to this problem without resort to extreme measures, and our hospitals are peculiarly

situated to take the lead, if not for plain moral reasons because they dispose of the best in medical talent, investigative facilities and educational arrangements.

Isolation and segregation of patients, except for contagious disease, should be associated with the past and not with the future. There is a wholesome tendency these days to draw all special hospitals, sanatoriums and asylums into the orbit of the general hospital. Another tendency is the replacement of the term cure by the newer term rehabilitation since we are committed to the total cure of all patients by total means and their restoration to full or at least partial, service in the community.

The problem of the alcoholic patient in relation to the hospital must be faced squarely. The committee is now engaged in seeking the facts about the hospitalization of the alcoholic, and since it will doubtless uncover an almost universal negative attitude toward this problem we shall expect a series of recommendations for the consideration of the American Hospital Association. Every hospital executive, every clinician, every social worker and every public spirited citizen who has dealt with this problem and is willing to give his best thought to its solution should cooperate with this committee for only in this way can we do our duty in this forsaken field and escape the condemnation of future generations.

E M BLUESTONE, M.D. New York
Director, Montefiore Hospital Chairman of the Committee

ICTERUS INDEX

To the Editor—In contemporary medical literature we find a lively interchange of the expressions 'icterus index' and 'icteric index' with the apparent indication that these terms are synonymous. Perhaps it is time to remind authors that the proper expression is 'icterus index' and not 'icteric index'.

In THE JOURNAL of July 3 is an article 'Pyuria of the New-born Treated with Sulfathiazole' by Florman and Bass in which 'icterus index' is mentioned in case 1 and 'icteric index' in case 2. These terms are not interchangeable and do not mean the same thing. Again in the text of 'The Physiological Basis of Medical Practice' by Best and Taylor ed 3, 1943, we find the 'icteric index' mentioned on page 780.

'Icteric' is an adjective and means relating to or marked by jaundice (Stedman), while 'icterus' is a noun meaning jaundice. 'Icterus index' means the index or measure of jaundice. We must remember that it is the patient who is 'icteric' (or jaundiced) and not the index. With this thought in mind, I am sure that the expression 'icteric index' will gradually fade into oblivion.

SAMUEL WIDMAN, M.D. Brooklyn

USE OF SULFONAMIDE POWDERS IN OTOLARYNGOLOGY

To the Editor—In a communication in THE JOURNAL, July 3, page 695 certain disadvantages arising from the local use of sulfonamide powders in otolaryngology are pointed out. The experiences which my associates and I have had with the powder blower method of therapy have not revealed these disadvantages.

Of 18 patients thus treated only 5 showed the presence of the drug in their blood streams at the end of twenty-four hours. In none of these did the value exceed 0.9 mg. per hundred cubic centimeters. In addition the patient must of necessity hold his breath during the treatment or the tracheal reflex will make it impossible to continue with the procedure. Therefore we feel that during treatment little if any, of the powder is aspirated.

MARVIN S. FREEMAN, Lieutenant, M.C.A.C.S.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Basic Science Law (Washington) Constitutionality, Validity of Requiring Examination in Chemistry—Ellestad sought by virtue of a license to practice chiropractic in Nevada to obtain by reciprocity and without examination a license to practice chiropractic in Washington. The director of licenses of the state of Washington refused to issue the license until the chiropractor had taken and passed the examinations in anatomy, physiology, chemistry, pathology and hygiene required by the Washington basic science act as a condition precedent to licensure to practice any form of the healing art. The chiropractor then brought an action under the Washington declaratory judgment act to test the constitutionality of the basic science act. He alleged that the act was unconstitutional and void because it violated the due process and equal protection clauses of both the state and the federal constitution and further because it was discriminatory in operation constituted class legislation and was arbitrary and unreasonable. The trial court dismissed the action and the chiropractor appealed to the Supreme Court of Washington.

The specific question presented for our determination and the Supreme Court is whether the requirement in the basic science act of an examination in the basic sciences of anatomy, physiology, chemistry, pathology and hygiene as applied to a person seeking a license to practice chiropractic violates such person of the due process clause or of the equal protection of the laws in violation of the state and federal constitution. This question has been squarely decided by this court in 1941.

W. Chinger, 182 Wash 360 47 P (2d) 35, in which it was held that the basic science act, as applied to a chiropractor, was constitutional and valid. Seventeen states and the District of Columbia have adopted basic science laws of varying degrees of similarity to our own. Up to the present time the constitutionality of these basic science laws has been questioned in only three states, including our own, and in every instance these laws have been upheld as constitutional. *State v. Wehinger*, supra, *State v. Broden*, 181 Minn 341, 232 N W 517, *State ex rel. Shenk v. State Board of Examiners in Basic Sciences*, 189 Minn 1, 250 N W 353, *State v. Ullke*, 202 Minn 114, 277 N W 420, *Shoud v. Crowe*, 199 Ark 814, 136 S W (2d) 1025. In the *Shenk* case, supra, in which the law was applied with reference to a naturopath, the Supreme Court of Minnesota said:

There is claim for petitioner that the basic science law is unconstitutional because abridging his privileges and denying him due process and equal protection of law. The point is without merit. The law does not limit naturopathy. It does regulate it. We are not interested in the extent to which the medical profession may have sponsored the law, nor their motives in doing so. It is enough that, since the days of Hippocrates, through those of Galen, Vesalius and their modern successor anatomists, there has been great progress and splendid accomplishment in their science and the related arts of diagnosis and treatment. Lawmakers everywhere have taken note and have been doing so for a century or more. They began by laws facilitating the procuring of human bodies for dissection.

Other laws, regulatory and otherwise, followed. Finally came the restrictive regulation through licensing, now familiar law everywhere. The basic science statute is the latest addition thereto. It departs some what from the older definition of the practice of medicine. Of its newer and broader category of the practice of healing, naturopaths have no complaint on constitutional grounds.

The chiropractor attacked the decision of the Supreme Court of Washington in the *Wehinger* case, supra, and likewise criticized the decisions by the other courts, on the ground that they failed to take into consideration the fundamental distinction between medicine and chiropractic, and that, on the contrary, they assume that there is no difference between medical anatomy, physiology, pathology and hygiene, on the one hand, and chiropractic anatomy, physiology, pathology and hygiene, on the other. The chiropractor then set forth the medical definitions of the five subjects specified in the basic science law and contrasted them with chiropractic definitions of the same subjects. The five subjects named in the basic science law, said the Supreme Court, pertain to separate and distinct fields of science. These sciences are, in themselves, exact and universal, and their principles operate with uniformity on the human body, regardless of the method of healing, or treatment, employed. The method of healing is simply the practitioner's art, as distinguished from the sciences which deal with the structure, composition, functions, diseases and sanitation of the body. It may be said, broadly, that chiropractic places the emphasis of its study and treatment on the spinal column, including the brain, the spinal cord and spinal nerves, while the school of medicine does not so restrict its field of either study or treatment. Whatever may be the extent of the difference of view between the two schools, whether of kind or of scope, the chiropractor's real objection here is that the basic science law requires him to take an examination which is broader in scope than the chiropractic field of study and treatment. The stumbling block, so far as he is concerned, is thus one of general educational requirements. The various professions, particularly those involving the healing arts, have long been the subject of regulatory legislation setting out requirements for the granting of licenses to practice such professions. As is stated in *Rottschaefer*, Constitutional Law (1939), pp 468, 469:

The requirement of a license necessarily involves a control by the government of who shall be permitted to pursue the licensed business or calling. Its aim is the protection of the public against injuries that it might suffer from the conduct of such business or calling. The state may, therefore, impose any conditions precedent to the grant of its consent which have a real and substantial relation to that objective. The principal field for the application of these principles has been in prescribing minimum standards of professional competence for such professions as the practice of medicine, dentistry, pharmacy, optometry, veterinary medicine, law, accountancy, and many others.

The legislature, continued the court, may therefore prescribe the standard of knowledge required of applicants for license to practice any of the healing arts, and the fact that it is broader in scope than the training which is given in chiropractic schools is not of itself enough to invalidate the legislative prescription.

It is sufficient if the requirements have a real and substantial relation to the objective sought, which is the protection of the public health and welfare. It is to be remembered that by the basic science act the legislature has prescribed one examination for all who desire to practice the healing arts, regardless of the school from which they come or the system which they desire to follow. The legislature must have intended thereby to set up a standard of basic, fundamental knowledge required of all practitioners of the healing arts in order to protect the public against incompetent attendance on human ailments.

The court of civil appeals of Texas, continued the Supreme Court, in *Johnson v. State*, 267 S W 1057, 1061 (1924), in a case in which a chiropractor urged that chiropractic is sufficient in all its requirements thoroughly to prepare the student for this special branch of the healing art and that the right to have this special branch recognized by law was denied by requiring an examination before a medical board, said:

Regardless of the school of medicine or system of practice followed by the practitioner of medicine in any of these systems the general welfare of the people demands that such practitioner be able to detect, readily, the presence of disease and to treat it in some manner recognized as appropriate for its removal. In order that assurance may be had that the one who treats diseases has this requisite qualification, the state has the undoubted right to prescribe a general preparation to be made by one entering such profession, and also to prescribe that he shall have a knowledge of what the legislature may deem the necessary scientific branches of such profession. The fact that it [the law] requires a broader education than is given by the chiropractic college to meet these conditions cannot be urged as a discrimination against such schools of medicine.

The authorities, continued the court, are uniform to the effect that the legislature may adopt such regulations and restrictions of the healing arts as they may consider necessary for the public good, and the courts will not question the wisdom or desirability of such legislative requirements, so long as there is any reasonable basis on which the legislative determination can rest.

The chiropractor contended further that in the *Wehinger* case previously decided by this court this court did not squarely meet the argument that the addition of chemistry to the list of subjects as one of the basic sciences is an unreasonable requirement. The chiropractor argued that chemistry does not enter into the principle and practice of chiropractic. Chemistry, answered the court, may not enter into the theory and practice of chiropractic, but every law of which we are aware providing for the licensing of chiropractic provides for learning in some subjects other than the theory and practice of chiropractic. The legislature set out the requirements for all practitioners of all schools of the healing art in the basic science act. It is the relation of chemistry to this basic fundamental knowledge that is important and to which we must look, and not the relation of chemistry to the particular school of learning. The court certainly cannot say that it is unreasonable to require a knowledge of chemistry on the part of those who deal with human life and diseases.

The court therefore held that the basic science act did not offend the constitutional provisions relied on by the chiropractor and that, regardless of the wisdom or propriety of the basic science law, its enactment was within the valid exercise of the police power of the state. Accordingly the court affirmed the judgment of the trial court against the chiropractor—*Ellstad v. Swavze, Director of Licenses*, 130 P (2d) 349 (Wash., 1912).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (9 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Capnograph String Galvanometer for Recording Arterial and Venous Pulsations. C. Fenning—p. 522

Subacute Bacterial Endocarditis—Held and Lieberson maintain that subacute bacterial endocarditis is a distinct entity. The vegetative endocarditis with its exudation of fibrin, blood platelets and enmeshed bacteria represents a state of high local and general tissue immunity rather than lowered resistance. The immunity resides in the local endothelial structures as well as in the general reticuloendothelial system. Since the reaction to this bacterial invasion is largely endothelial, the disease may be termed infectious endotheliosis. Subacute bacterial endocarditis occurs in patients with valvular disease, usually rheumatic, but who have acquired a high degree of immunity, so that reinfection, recurrent endocarditis or pancarditis and congestive heart failure do not occur. This increased immunity is responsible for the fact that the patient is not heart-conscious even during the attack of acute valvular infection. A transient bacteremia caused by an upper respiratory infection, tonsillectomy, extraction of an infected tooth or pyelitis, permits secondary invasion and implantation of bacteria, usually of *Streptococcus viridans*, on the damaged valve. A careful history will reveal that some infection which lowered the general body resistance is usually the beginning of an illness that later develops into subacute bacterial endocarditis. Although the bacteria are able to implant themselves on the damaged valves, they find there an altered tissue reactivity which does not permit much local damage, such as ulceration or extension into the myocardium or pericardium. A more favorable outcome would be likely if the bacteria were not localized in a focus that communicates directly with the blood stream. If embolism does not cut the disease short, death occurs when the local and systemic endothelial systems become exhausted. Subacute bacterial endocarditis is a true endocardial sepsis for the valve acts as the primary distributing focus of the infection. If the focus can be removed surgically (as in some cases of patency of the ductus arteriosus) or chemotherapeutically before complications set in there is some hope for cure.

Pancreatic Tissue Extract in Peripheral Arterial Disease—Gorham and Climenko present proof of the physiologic activity of a new and potent pancreatic extract which is free from insulin and histamine. It has been shown to cause peripheral vasodilatation in the limbs of animals and normal human beings, as measured by an increase in volume and a rise in

temperature. The authors report the results obtained with the pancreatic extract in 21 cases of peripheral arterial disease. There were 15 instances in which the response to cold was of the spastic type. These patients reacted especially well to the extract, all of them showed significant increases in limb volume and rises in skin temperature. Symptomatic relief was complete in 8 cases and partial in 4. The 3 patients in the "spastic group" who failed to benefit symptomatically had Buerger's disease or thrombophlebitis. Six patients in the series of 21 gave a normal response to cold stimulation, that is, they showed no evidence of vasospasm. None of these patients received any benefit from injections of the pancreatic extract.

Tuberculosis in Industry. H. R. Edwards—p. 571

Focal Necrosis of Adrenal Cortex—The 18 cases of focal necrosis of the adrenal cortex reviewed by Mitchell and Angrist represent lesions discovered during 3080 routine necropsies. With the exception of 1 case all lesions were seen microscopically in a single section of the adrenal gland. All lesions were studied on formaldehyde fixed paraffin embedded material stained with hematoxylin and eosin. Giemsa and Gram stains were done on lesions showing recent changes. Eleven females and 6 males comprise the series. The ages range from 14 months to 84 years. The lesions were of recent origin in 12 instances and showed evidence of chronicity in 5. The acute changes were of 2 types. The first consisted of a focal coagulation necrosis of the adrenal cortex tissue. They were encountered mainly in the zona fasciculata but were also seen in the other two layers and in 1 instance reached to the capsule. Some of the zones of necrosis bore a distinct resemblance to tubercle structures. Complete examination in the cases failed to reveal any active or inactive tuberculosis and stains for acid fast bacilli were negative. The other type of acute change was one of localized cytonecrosis of a varying number of individual cortical cells. In the literature focal necrosis of the adrenal has been associated with actual infection or toxic states. Eleven of the reviewed 12 cases showing recent changes had some infectious disease varying from limited lobular pneumonia to extensive suppurative peritonitis. It is the authors' impression that endocrine abnormalities contribute to the evolution of focal necrosis. Diabetes mellitus was noted in 5 of the

cases, and no infectious process was present in 2. In 1 of the latter Cushing's syndrome was fully developed, and the diagnosis of basophilic adenoma of the pituitary was confirmed at necropsy. In the other instance an eosinophilic adenoma of the pituitary was noted. The authors believe that a physiologic component in the production of the necrotic lesions is indicated by the multiplicity of etiologic factors, the apparent significance of adrenergic states and the gradation of such lesions in size and nature with myelohyaline physiologic changes in the adrenal, and the negative bacteriologic and virus findings. The possible significance and the relationship of such lesions to Addison's disease and to Waterhouse-Friedrichsen syndrome and to intestinal ulceration is intimated.

Vitalium Tubes for Blood Vessel Anastomosis— Blakemore and his associates report the use of vitalium tubes as prosthesis in blood vessel anastomosis in dogs. Vitalium is a nonirritating alloy suitable for a vein graft or for bridging an artery or vein defect in a nonsuture method of vessel anastomosis. Carefully controlled experiments on dogs demonstrated that sulfathiazole by mouth contributes greatly to the success of delayed anastomoses of severed vessels in contaminated wounds. They administered sulfamidamide in alternate wounds in a series of seventy-seven anastomoses and found it to be of moderate but definite value. The nonsuture method was shown to be highly successful in anastomosing the small femoral arteries of dogs even in contaminated wounds twenty-four hours after section of the artery and without the use of anticoagulants. Vein graft anastomosis of a severed primary artery in the war wounded would prevent the loss of the extremity by gangrene if the anastomosis remained patent beyond the period of posttraumatic edema, up to fourteen days. Veins taken from one dog continued to function in another when used as transplants to bridge vessel defects. These experiments afford a prospect for the use of preserved veins as grafts for bridging vessel defects in the war wounded as an alternate to the use of homoplastic transplants.

Nitrogen Balance, Caloric Intake and Weight Loss in Postoperative Convalescence— Mulholland and his collaborators determined the nitrogen balance in 8 cases of duodenal ulcer after partial gastrectomy. Four patients were given the postoperative ward routine of infusions, occasional blood transfusion, and a gradually increased oral feeding. This group served as control. In another group of 4 cases a high caloric

and high nitrogen feeding was given to replace the nitrogen loss so that at the end of the postoperative period of ten to twelve days a nitrogen surplus was accumulated in the body. The nitrogen balance, body weight and plasma proteins were determined for both groups periodically throughout the convalescent period. The fluid intake and output were followed and the caloric and sodium chloride intakes were noted. The chief sources of nitrogen loss were recorded. The number of days of hospitalization of one group was compared with that in the other. All cases in the control group exhibited a cumulative nitrogen deficit, a progressive loss of body weight and a suggestive progressive fall of plasma protein concentration. In the group in which the caloric and nitrogen balance were maintained by tube feeding with an easily assimilable feeding mixture there were achieved a positive nitrogen balance, a cumulative nitrogen surplus and a progressive rise of body weight and of plasma proteins. There also seemed to be the minimum amount of postoperative asthenia. The authors stress the fallacy of expecting to maintain nutrition by blood transfusions and the necessity of a higher 'lower limit of normal' of plasma proteins for surgical patients.

Hereditary Corneal Dystrophy—Schutz directs attention to a hereditary type of corneal dystrophy which he recently observed in a family. Out of 15 adults and 6 children of this family 11 of the adults had the disease. One other member not examined is said by the family to have the disease. None of the 6 children presented the lesions. The condition is a hereditary disease with a mendelian dominance. Consanguinity is not a factor. It affects males and females equally, is bilateral, is more or less symmetrical and is central in position. The corneal surface is smooth and its sensibility is not diminished. There is no history of irritation and no evidence of inflammation. The visual acuity is unaffected in the younger members and only slightly so in the older. The reticular nodular and ring shaped varieties may coexist in members of the same family and even in the same person. Bücklers classified hereditary corneal dystrophy into the crumblake type, the macular and the lattice-like. In the crumblake type the visual acuity and corneal sensibility may be only slightly diminished late in life. It does not lead to blindness. The inheritance is dominant. In all the cases in the present series the disease was of Bücklers' type 1. The prognosis is good. The other two types lead to blindness. The macular type of corneal dystrophy leads to early diminution of visual acuity with diffuse and rapid clouding of the cornea and early loss of sensibility. Inheritance of this type is recessive and the lesion need not appear in every generation. The lattice-like corneal dystrophy produces irregularity of the cornea early in life with corresponding diminution of visual acuity and early loss of corneal sensibility.

Ascorbic Acid in Secretion of Intraocular Fluid—Friedenwald and his collaborators demonstrated that the interstitial tissue of the stroma of the ciliary processes contains a group of reducing substances one component of which has been identified as ascorbic acid. These substances act as a mediating system facilitating the oxidation-reduction interaction between the stroma cells and the stroma-epithelium barrier. Elimination of vitamin C from the diet of guinea pigs leads to the disappearance of this substance from the ocular tissues long before any constitutional symptoms of scurvy develop. The loss of ascorbic acid from the secretory system in the eye results in a decrease in the rate of transfer of basic dyes from stroma to

epithelium and in a decrease in the rate of secretion of the intraocular fluid. Ascorbic acid is stored in the ciliary stroma, being reversibly bound by an acidophilic component of this tissue. Oxidation of ascorbic acid by the ciliary epithelium is probably a necessary step in the intraocular secretion of this substance. The secretory mechanism of the ciliary body in the cat conforms in pattern to that in the rabbit and in the guinea pig but the redox potentials of both epithelium and stroma are considerably more negative than the normal potential of ascorbic acid. Consequently ascorbic acid does not act as a mediator in this system.

Visceral Lesions in Chronic Infectious Arthritis—Baggenstoss and Rosenberg studied at necropsy the anatomic changes in the viscera of 30 patients with rheumatoid arthritis. The mean age of the patients at death was 37.6 years, the youngest was 9 the oldest 81 years of age. 11 were less than 40. Rheumatic heart disease was present in 16 and other cardiac lesions in 8. Pulmonary diseases present included bronchopneumonia, fibrous pleuritis, bronchiectasis, pulmonary embolism and fat embolism. No characteristic hepatic lesion ascribable to rheumatoid arthritis was observed. The alterations present were hypertrophy, atrophy, chronic passive congestion, fatty change, central necrosis, amyloid deposits, subacute yellow atrophy, healed miliary tuberculosis and the serous hepatitis or Rosell and Eppinger. The lymph nodes and the spleen though occasionally enlarged during life, showed only various nonspecific inflammatory and degenerative effects: proliferation of reticulo-endothelial tissues, degeneration of lymph follicles, amyloid deposits, suppurative lymphadenitis, hypertrophy (or the spleen) and chronic passive congestion. A low grade nonspecific glomerulonephritis was present in 19. Other renal lesions present were chronic or subacute interstitial nephritis, non-suppurative pyelonephritis, amyloid degeneration, nephrolithiasis with acute pyelitis and dissecting aneurysm of the right renal artery. Various lesions of minor importance were encountered in the other organs.

Vitamin C in Raw Cabbage and Home Canned Tomato Juice—Clayton and Borden investigated the availability of vitamin C in raw cabbage and home canned tomato juice on four young, healthy subjects. The utilization of the vitamin C

of each test food was compared with that of pure vitamin C tablets. The basal diet used was neutral in reaction and the subjects were saturated before each test period. Judging from the results of both blood and urine analyses, the vitamin C of both raw cabbage and tomato juice was utilized as well as, or possibly better than, that in the tablets. An average of 116 Gm of the cabbage or 208 cc ($\frac{3}{4}$ cup) of the tomato juice used in this experiment provided 50 mg of vitamin C.

Congenital Cysts of Mediastinum—Carlson discusses mediastinal cysts and cystic tumors believed to be the result of some aberration in embryologic development. The bronchial and gastrointestinal cysts, the entodermal cysts, differ from teratomas in that they do not contain tissue derived from ectoderm, they reproduce the structures of the bronchus, stomach or bowel, they occupy a posterior position in the mediastinum and often cause symptoms, serious complications or death in early infancy. They are believed to originate from the foregut, the respiratory buds or their derivatives (bronchial cysts) or from the omphalomesenteric duct (gastric and enteric cysts). By contrast, teratomas contain tissue derived from ectoderm (usually mesoderm, often entoderm). They have the structure which the name implies. They arise in the anterior mediastinum and frequently do not produce symptoms for a period of twenty to forty years. They are believed to develop from cells which have become segregated early in embryonic life. The author reports 3 cases. 1 A man aged 23 was found on x-ray examination of the chest to have a tumor mass suspected of being a dermoid cyst. The cyst was removed and was discovered to be a teratoma. 2 An 8 month old male infant had difficulty in breathing and died three days after hospitalization. The necropsy disclosed a bronchial cyst of the mediastinum with compression of the trachea and main bronchi, acute emphysema of the anterior portion of both lungs, acute bilateral hypostatic bronchopneumonia and acute catarrhal tracheobronchitis. 3 An infant aged 4 months had labored breathing and difficulty in swallowing. The removed structure proved to be a gastric cyst. The author discusses exteriorization and drainage of such cysts.

Kidney in Hypertension—McMartin and McCurdy maintain that hypertension may have its source in one kidney. They cite 4 cases of unilateral renal disease in which hypertension developed. They conclude that hypertension resulting from disease of one kidney is not the rule but is frequent enough to cause one to bear in mind the urologic tract as the source

The background changes of hypertensive patients will regress toward normal if the responsible kidney is removed before arteriolar disease of the other kidney gets under way. Urologic examination should be done before referring the hypertensive patient for denervation operations or medical therapy. Patients who have had pyelolithotomy, nephrolithotomy, drainage of perinephric abscess, plastic operation on the pelvis of the kidney, nephropexy and the like should have their blood pressure checked at regular intervals so that the onset of hypertension may be detected early and the source which may be the kidney previously operated on, removed.

Diagnosis and Treatment of Ludwig's Angina—Williams and Guralnick report a series of 20 cases of Ludwig's angina treated at the Boston City Hospital from June 1939 to June 1942. The mortality in this series was 10 per cent. Mortality in a previous series of 31 patients was 54 per cent. Emphasis is placed on the role of teeth and dental procedures as etiologic factors. Some type of dental lesion was the initiating factor in 18 of the 20 patients (90 per cent). Streptococci were present in all and both streptococci and Vincent's organ-

isms in 8 of the 16 cases in which bacteriologic studies were made. Employment of both cultures and smears taken at operation is urged as a basis for the choice of dressings post-operatively. Zinc peroxide dressings are recommended when anaerobes are demonstrated. The authors advocate radical surgery as soon as the diagnosis is established, exposure of the trachea or a tracheotomy previous to the operation. Intravenous pentothal sodium is the anesthetic of choice. The use of sulfonamide drugs orally or parenterally is strongly favored. Dependence on sulfonamides without surgery, however, is discouraged. Under the regimen advocated the ordinary complications of Ludwig's angina have been eliminated.

Addison's Disease Report of Fatal Case H A Lawson, L A Beck and R G Murphy—p 480

Pulse and Blood Pressure in Relation to Physical Fitness in Young Men—Brouha and Heath made studies on 265 college students. They found a wide variation in the pulse and blood pressure in normal, healthy young men. Although the values far exceed the usually accepted norms, they are nevertheless compatible with normal physiologic reactions to emotional stress and hard muscular work. There is no satisfactory relation between basal pulse, sitting pulse and physical fitness for strenuous exertion in normal healthy young men. There is no relation between sitting systolic or diastolic blood pressure and physical fitness for strenuous exertion in normal, healthy young men. Emotional factors are largely responsible for high resting pulse rates commonly found during the pre-induction medical examination of healthy young men. Resting pulses above 100 and sitting systolic blood pressures above 140 mm are not exceptional in medically normal subjects when exposed to some emotional strain, and in many of them they accompany an average or good physical fitness for hard muscular work. In normal young men no measurement of pulse or blood pressure taken at rest is indicative of capacity to perform hard work. When the resting pulse or blood pressure is unusually high it is recommended that the subject be submitted to a standard amount of strenuous exercise. The estimate of capacity to do hard muscular work should be based on the subject's actual ability to perform it and on the speed of recovery of his heart after exercise rather than on resting values of pulse and blood pressure alone.

Threatened Abortion—The results of treatment of 140 patients with threatened abortion in 870 consecutive pregnancies form the basis of this report by Silbernagel and Burt. Vaginal bleeding, with or without cramping, was the only criterion for the diagnosis of threatened abortion. Bleeding due to local lesions was excluded. Basal metabolism determinations were made in every case and sufficient thyroid or strong solution of iodine was administered to bring the basal metabolic rate to approximately plus 5 per cent. At the first sign of bleeding the patient was immediately put on absolute bed rest. No opiates were used. An ice bag to the lower abdomen was used to control pain. If necessary barbiturates were given to provide rest and relaxation. This was the only treatment employed in a control group of 50 patients (357 per cent of the series). Of these 47, or 94 per cent, aborted. The authors report their experience with the parenteral administration of progesterone, the intramuscular injection of alpha-tocopherol acetate alone or in combination with the natural tocopherols and synthetic alpha-tocopherol acetate, the oral administration of natural tocopherols or of alpha-tocopherol acetate and the treatment with freshly extracted wheat germ oil by mouth. With the use of progesterone 182 per cent went to term. The authors feel that this is not a sufficient percentage of salvage in cases of threatened abortion to warrant the routine use of progesterone. A certain number of abortions are inevitable as the result of maternal, fetal or chorionic causes. Therapy of these is valueless. The intramuscular use of alpha-tocopherol acetate alone produced a salvage of only 20 per cent. Alpha-tocopherol acetate used alone, both intramuscularly and orally, produced a continuation of pregnancy in 66⅓ per cent. The intramuscular use of alpha-tocopherol acetate combined with the oral administration of the natural tocopherols produced a salvage of 85.7 per cent. The oral administration of alpha-tocopherol acetate alone allowed 167 per cent of the pregnancies to continue. This was nearly as effective as progesterone alone. The oral use of natural tocopherols produced a salvage of 42.8 per cent and the use of wheat germ oil alone saved 33⅓ per cent of the pregnancies.

Roentgen Treatment of Acute Bursitis of Shoulder—Harris reports gratifying results from the roentgen treatment of 40 cases of acute calcified bursitis of the shoulder. The acute cases give the best results. The chronic cases are improved. The therapy consists in daily treatments for three or four days, 250 roentgens as measured in air is given in each treatment. The kilovoltage employed is unimportant, provided sufficient filtration is used. The author used 200 kilovolts with 0.5 mm of copper plus 1 mm of aluminum filtration and 120 kilovolts with 5 mm of aluminum filtration. The results have been equally good. Within twenty-four to thirty-six hours there was definite relief from pain, and by the end of the third day the severe pain has disappeared. There remains a stiffness which gradually subsides. Most patients use the arm in a normal manner in a week to ten days. The calcium is slowly absorbed. In the cases examined it has completely disappeared in three to four months.

Dermatitis from Airplane Engine Covers—According to Schwartz and Peck, airplane engine covers are being extensively used to replace the usual antirust compounds with which engines are covered before they are shipped to the assembly plant. The covers are made of phtofilm, a material that has been in use for many years with no record of resultant dermatitis. Phtofilm has been recommended as a suitable material for sleeves and aprons to protect workers against industrial skin irritants. A chemical known as R M F was added to the special phtofilm for engine covers to prevent the phtofilm from deteriorating when exposed to light. An outbreak of dermatitis was observed among workers manufacturing airplane

engine covers made from this special phofilm. Tests revealed that the R M F was the cause. This substance is both a primary irritant and a sensitizer. To prevent further attacks of dermatitis it is suggested that workers handling phofilm containing the R M F should wear protective sleeves and aprons made of ordinary phofilm, mylite, koroseal or laminated cellophane. The hands may be protected by gloves made of washable leather or finely knitted cotton. Persons on the job of heat sealing can protect their faces from the irritant fumes developed during the operation by the use of a protective ointment of the invisible glove type. Workers who continue to have dermatitis after observing the recommended precautions should be removed from further exposure to the material.

Murine Typhus Fever Control—Eskey states that during the period from 1932 to 1941 approximately 20,000 cases of murine typhus fever were recorded officially in the United States. Although the European or epidemic typhus has a much higher death rate than the murine typhus, the latter should not be regarded lightly. In a patient with murine typhus is more than 60 years old the chances of recovery are not good, young adults are usually acutely ill for two weeks. The febrile stage is commonly followed by a period of convalescence of two months or more before the patient fully regains his strength. Most cases of human infection with the rickettsiae of murine typhus are traceable to typhus infected domestic rats. Control of the disease therefore is based on the difficult task of eradicating the rodent reservoir of infection. During 1941 only 2 per cent of the reported cases occurred in states north of a line extending across the country at the level of the southern boundary of Kentucky. Only 18 per cent of the cases were reported from the area between this line and another line traversing the northern boundary of Louisiana, that is in the territory between 36° 30' and 33° north latitude. In the region south of 33° north latitude, murine typhus is most prevalent.

Sulfadiazine and Sulfanilamide Intraperitoneally—Walter and Cole implanted sulfadiazine crystals in the peritoneal cavity and wounds of 68 patients operated on for various lesions most of which caused peritoneal contamination. A similar procedure using sulfanilamide was carried out on 62 patients. There was an incidence of 4.04 per cent of wound infection in the sulfadiazine group and of 14.05 per cent in the sulfanilamide group. Sulfadiazine appeared superior to sulfanilamide in the prevention of wound infection. One instance of wound disruption and 1 of total peritonitis in that series were probably not related to the use of the drug. There were no toxic manifestations and no evidence of delay in wound healing in the sulfadiazine group. A dose of 6 Gm was adopted as the routine 4 Gm being placed in the peritoneal cavity and 2 Gm in the layers of the wound. The studies on animals and on human beings revealed a much more persistent blood level with sulfadiazine than with sulfanilamide. Sulfadiazine is also less toxic. The longer persistence of the blood level of sulfadiazine over sulfanilamide makes the former drug superior for implantation in the peritoneal cavity and wound layers in a laparotomy. Use of sulfonamides in wounds contaminated by bowel resection has resulted in a much lower incidence of infection sulfadiazine being superior to sulfanilamide.

Melanopithelioma of Extremities—Bickel and his collaborators reviewed the clinical and pathologic material in a series of 155 cases in which diagnosis of melanopithelioma of an extremity was made at the Mayo Clinic during the twenty-four year period from 1916 to 1939 inclusive. In this series 29.8 per cent of the patients treated by excision survived five years or more. There were many cases in which the lesions were small and the patients were seen in the early stages of the disease. Amputation was the most common type of treatment for cases in which the lesion was more extensive and of a longer duration, yet in this group there was a five year survival rate of 21.1 per cent. None in the group treated by irradiation alone survived three years. A melanopithelioma may be present for a long time before the seriousness of its nature is recognized. The condition may be activated by middle-aged treatment. The treatment of choice is a wide excision with removal of regional lymph nodes or amputation. When tumors do not appear to be increasing in size or showing evidence of ulceration a wide local excision would appear adequate.

Tannic Acid and Liver Necrosis—Forbes and Evans point out that subcutaneous administration of tannic acid in rats results in liver necrosis. They suggest that liver necrosis noted in many cases of severe burns may have been due to the toxic action of the tannic acid rather than to toxic products arising from the burned tissue. Observations on six series of rats demonstrated the hepatotoxic action of subcutaneous tannic acid injections. No protective action resulted from either the oral or the subcutaneous administration of sulfanilamide or from the subcutaneous administration of xanthine.

Intra Group Incompatibilities in Whole Blood Transfusions—According to Houghan, an appreciable number of transfusion reactions are caused by intra group incompatibilities. The detection of subgroups A₁ and A₂ should be performed routinely on patients receiving multiple transfusions and on patients in whom incompatibility due to the Rh factor has been eliminated. Most of the intra group reactions are due to Rh incompatibility. Every attempt should be made to employ the present methods for the detection of Rh agglutinogens and agglutinins. Serum containing Rh agglutinins can be used to detect the Rh antigen in donors and laboratory personnel. Rh agglutinins can be detected in the patients' serum by the cross matching tube technique of Landstemer and Wiener. An attempt should be made to check prior to the transfusion the Rh status of every patient who has had an irregular or pathologic obstetric course, whose history shows previous miscarriages or abortions of unexplained nature or who has given birth to infants with erythroblastosis.

Vaginal Tampons in Menstrual Hygiene—Singleton and Vanorden sent out a questionnaire on the subject to 3,400 members of obstetric and gynecologic societies and to about 500 doctors in general practice. Physicians were four to one against the use of menstrual tampons. Some few favored or permitted it with limitations, such as during the early and last days of menstruation, for esthetic reasons to dancers, actresses, for athletic events, and the like. There was an almost unanimous opposition to the use of tampons by virgins because of a feeling that it created sex consciousness and stimulated eroticism and the habit of masturbation. The difficulty of application was stressed. Tampons, if used, should be changed frequently, since blood clots often form on the tampon and may therefore cause a back flow of menstrual discharge through the uterus and tubes into the peritoneal cavity, this possible origin of endometriosis was repeatedly stressed. Twenty per cent of the physicians reported instances of pathologic changes varying from a mild vaginitis to a pelvic infection. Many instances of lost or retained tampons were recorded. There appears to be a definite potential source of infection in the habitual or occasional practice of menstrual tamponage. Preexisting infections may become aggravated.

Vaginal Tampons for Menstrual Hygiene—Karnaky carried out careful studies on 218 women who used tampons during their menstruation for one year and over. No irritation, discharge, vaginitis or cervicitis was found. A series of 42 women were instructed to insert a large tampon night and morning every day in the interval between their periods and during their menstruation. These tests ran from six months to two years. A bacterial culture was taken, the vaginal pH and the amount of glycogen were determined, and a vaginal biopsy was made and notes on the local examinations were recorded before, during and after the use of the tampons. These observations were carried out at two to four week intervals. With hardly an exception, the findings were favorable. The tampons did not block the flow nor did they irritate the vaginal tissue. Of the 110 young nurses, 95 per cent used tampons with satisfaction all through menstruation. Only 5 per cent could not use tampons in the middle of menstruation because of an excessive flow. The tampons are comfortable and overcome the problem of menstrual odor.

Sputum Examination in Carcinoma of Lung—According to Sambrook Gower examination of sputum by the smear method of Dudgeon is of great value for the early diagnosis of malignant growth. The sputum should be expectorated first thing in the morning so that there is no contamination with food particles. The specimen is to be coughed up. Preservatives or disinfectants must not be added and the specimen is to be examined as soon as possible after collection. Specimens collected at bronchoscopy or coughed up shortly afterward are suitable for examination. Dudgeon advises that the sputum be poured on to an unglazed porcelain tile to concentrate it but the author found that by examining it in a large Petri dish on a black background it was easier to pick out portions for examination. Blood streaked fragments or the more solid portions are picked out with a platinum loop or scalpel and are spread thinly on a slide. Several slides are prepared from each sputum. They are fixed by immersing at once in a bath of Schaudinn's solution and leaving for twenty minutes, washing in 70 per cent alcohol containing a trace of iodine to remove excess mercury bichloride (two minutes) and then in distilled water. The slides are stained with Mayer's hemalum (one and one-half to two minutes) blued in tap water counterstained with eosin (two minutes) dehydrated and mounted in Canada balsam. They are then examined with the low power of the microscope and any suspected group of cells is submitted to a higher magnification. When the clinical evidence is strongly in favor of carcinoma several specimens of sputum should be examined before a negative report is made. A negative report does not exclude malignant disease. The author used this method in 93 cases of suspected neoplasm of the lung. In 64.3 per cent of the cases he succeeded in demonstrating malignant cells. The cells were found not only in advanced cases but also in a significant proportion of those in which the growth was still operable. The test is of value in establishing malignancy when other methods of investigation including bronchoscopy have failed and when it is desired to explore the chest, for patients too ill to be submitted to other methods of investigation and when the growth is masked by secondary inflammatory changes in the lung. It is urged that the test be employed more widely and that aspiration biopsy should be reserved for cases giving repeatedly negative sputum tests and should not be employed when surgical removal of the growth is envisaged.

Clostridium Welchii Infection of Uterus—Rendle-Short reviews the literature on gas gangrene infection of the uterus following abortion or delivery and reports 6 original cases. The acute abdominal pain jaundice foul vaginal discharge rapid pulse possibly vomiting or diarrhea make a dramatic picture particularly if there are the additional signs of hematuria abdominal discoloration and gas escaping from the vagina. The fetus may or may not be distended with gas. In nearly all cases infection comes from outside following some manipulation instruments being contaminated by fecal matter on the vulval hairs. In rare cases there has been no outside intervention and in such cases Clostridium welchii was probably present in the vagina. If the fetus is dead the danger of infection is much greater. There are two main clinical groups one postabortal and the other puerperal the postabortal being slightly more common. The symptoms depend on whether the infection is local or generalized. Survival occurs in most of the 'local' cases death occurs in well over 50 per cent of those with physometra or generalized infection. Modern treatment makes the outlook much better. Great care should be taken when intervention is necessary when a dead fetus is known to be present. Serum and sulapyridine should be given prophylactically in a potentially infected case. Treatment consists in the prompt giving of anti-gas gangrene serum together with sulapyridine as soon as the disease is suspected without waiting for a swab report. Dextrose and fluids should also be given.

*Development of Cold Agglutinins in Atypical Pneumonia J C Turner—p 419

Development of Cold Agglutinins in Atypical Pneumonia—Turner points out that in addition to the classic iso-agglutinins that delineate the four primary blood groups of man there exist in many normal sera other substances which may cause clumping of erythrocytes. They are called cold agglutinins because in most instances their action appears only at low temperatures. Specific cold agglutinins concerned with the subgroups of type A blood have been distinguished. The cold agglutinins are, however otherwise considered to be non-specific as they will produce clumping of all human red blood cells irrespective of group. Since they likewise affect the cells of the individual in whose serum they appear they are sometimes named autoagglutinins. The detection of the cold agglutinins in 2 patients with atypical or virus pneumonia induced the author to search systematically for them in 22 cases of virus pneumonia. All the patients were soldiers in the overseas forces of the U S Army. Twenty-nine men with various infections served as controls. No less than 10 pneumonia sera produced a hard solid disk of agglutinated cells. This is in sharp contrast to the delicate clumping usually seen in the controls none of which showed a disk. On the basis of observations in several examples of atypical pneumonia coccic pneumonia it appears likely that the rise of cold agglutinins in the serum rises during the acute period of this disease in contrast both to the convalescent phase and to the acute phase of pneumonia.

Sulfanilamide and Antigangrene Serum for Putrid Empyema—According to Cistex and his collaborators the therapy of putrid empyema consists in repeated pleural punctures followed by injections of pure oxygen and of a mixture of sulfanilamide and antigangrene serum. A preliminary lavage of the pleural cavity with sulfanilamide in isotonic solution of sodium chloride in the proportion of 0.25 Gm of the former in 25 cc of the latter is indicated in the presence of thick pus. Pneumothorax is induced by intrapleural injection of 200 cc of air. In the presence of increased tension the air is removed during the puncture and an equal amount of pure oxygen is introduced. The mixture for each pleural injection consists of 4 Gm of sulfathiazole, 3 Gm of sulfapyridine, 1 Gm of sulfanilamide and 30 to 50 cc of polyvalent antimigraine serum. This treatment is given daily for twelve days, after which the serum is discontinued. The intrapleural administration of sulfanilamide is continued at intervals of two to four days or once a week until a cure is obtained as manifested by laboratory tests and by the sedimentation speed of the erythrocytes. Nausea, chills and dizziness are an indication for discontinuance of the serum treatment. The serum is temporarily contraindicated for patients with a bronchopulmonary fistula who require desensitization before recourse to the combined therapy. Blood transfusions, cardiac tonics and proper general care are indicated.

Desoxycorticosterone Acetate and Heart—Dassen warns against the simultaneous administration of desoxycorticosterone acetate and sodium chloride in the management of the crises of Addison's disease. The combined therapy produces a rapid dilatation of the heart, which, however, can be rapidly reversed through the omission of the adrenal preparation and its replacement with a diuretic followed by sodium chloride in 6 to 8 Gm daily doses. Desoxycorticosterone acetate alone is of value in the therapy of the Addisonian crises. The drug should be discontinued as soon as the crisis is over, after which sodium chloride is indicated. The patient should be placed on a diet containing large amounts of potassium for as long as he is subjected to the adrenal therapy and on a diet containing very small amounts of potassium when he is on the sodium chloride therapy. In the case reported the teleroentgenograms showed a rapid enlargement of the heart shadow during the combined desoxycorticosterone and sodium chloride therapy. The size of the heart diminished as soon as the desoxycorticosterone was omitted and a diuretic and sodium chloride were given.

Blood Sugar in Hepatic Insufficiency—Gohr and Schmitz investigated the diagnostic value of the blood sugar curve following oral tolerance tests with 40 Gm of galactose or 40 Gm of levulose. The tests were compared with the sugar elimination in the urine, with the flocculation reactions of Takata, Bauer and Weltmann and with the clinical course. In hepatic lesions accompanied by ascites or edema the elimination tests often gave inaccurate information. The blood sugar curve is only slightly influenced by these disturbances and is therefore useful in such diseases as well as in the various types of jaundice. The curves are protracted in hepatic insufficiency and

often reveal an abnormal increase in the blood sugar values. The galactose curve shows greater deviations from the normal than does the levulose curve and is therefore of greater diagnostic value. Forty Gm of levulose is inadequate for a tolerance test. Both curves correspond somewhat to the precipitation reactions of Takata, Bauer or Weltmann and like these they indicate impairment of the hepatic parenchyma. Extrahepatic factors may exert their influence. The blood sugar curve following the galactose tolerance test together with the precipitation reactions permit a true estimate of the hepatic function. The lactic acid content of the blood was determined during the precoma and the coma of 2 patients with hepatic cirrhosis who died in hepatic coma. Considerably increased values were ascertained.

Excision of the Superior Cervical Ganglion for Peripheral Facial Paralysis—Placinteanu and Dobrescu discuss the primary suture of nerve ends, transplantation of nerves, attachment of the peripheral end of the facial nerve to a neighboring cerebral nerve, the myoplastic method, the suspension method and the excision of the superior cervical ganglion in the treatment of traumatic peripheral facial paralysis. They are chiefly concerned with the procedure mentioned last, which was first employed by Leriche. Their first patient presented a paralysis of the left side of the face with extreme lagophthalmos and drooping of the left angle of the mouth. Electrical treatment was ineffective. Extirpation of the superior cervical ganglion was followed by reduction of the lagophthalmos, by miosis and hyperemia of the conjunctiva and of the paralyzed part of the face. The patient had a sensation of warmth and no longer felt the inertia of the paralyzed muscles. Complete closure of the palpebral fissure became possible in the course of time and the angle of the mouth could be voluntarily contracted. Three other cases are reported. The authors conclude that excision of the superior cervical ganglion is of real value in the treatment of peripheral facial paralysis. This sympathectomy is directed particularly against the lagophthalmos, which either disappears or is considerably reduced. If, as is sometimes the case, the paralysis of the angle of the mouth is not corrected, a myoplastic procedure might improve the results.

- Operative Treatment of Irreparable Transverse Lesions of Spinal Cord and of Paralysis Due to Injury to Nerve Plexus R. von Oppolzer—p. 545
- *Study of Joint Effusions From Accidental Injury Including Traumatic Serous Knee Joint Effusions W. Beyer—p. 551

Traumatic Joint Effusions—Beyer performed eighty punctures in 50 cases of joint effusions. One hundred and sixty preparations were studied. On the third day after the accident a lymphocytosis was manifest. Other parts of the body were not involved. Beyer considers lymphocytosis as a manifestation of a normal course of healing of blood effusion and not as a manifestation of transition to a chronic effusion. Within fourteen to eighteen days at the earliest the change to a serous, amber colored, limpid effusion may develop from blood effusion. Unless the history and the clinical picture correspond, one should refrain from a diagnosis of a traumatic serous effusion. History previous to the accident should exclude pain in the knee joint or damage to the joint. The interval between accident and effusion should not exceed twenty-four to ninety-six hours. External signs of injury are helpful. Synovial cells and some lymphocytes but little or no polymorphonuclear leukocytes should be demonstrated on cytologic examination. Internal damage to the joint should be excluded. More frequent cytologic examinations for serous effusions are recommended.

Book Notices

Essentials of Industrial Health By C O Sappington M.D. Dr.P.H. Consulting Industrial Hygienist President Central States Society of Industrial Medicine and Surgery Chicago. Pp 626 with 63 illustrations Philadelphia Montreal & London J B Lippincott Company 1943

The scope of industrial health has become so inclusive that it is not possible for one person to become a specialist in every branch of the subject. The author has drawn freely, with acknowledgment from literature to augment his experience in industrial health to compile this textbook. With this type of treatment, practical and pertinent data are presented in almost all phases with the retention of the uniform style and philosophy of the author.

The presentation of the material follows the Outline for the Teaching of Industrial Health prepared by the joint committee from the American Association of Industrial Physicians and Surgeons and the Council on Industrial Health of the American Medical Association. This has led to some unavoidable repetition but assured coverage in a manner suitable for the student. The principles and methods of industrial health contained in detail are informative to the practicing physician yet couched in language to be of use to laymen such as industrial personnel and attorneys.

The book is divided into three parts Industrial Health Administration, Industrial Hygiene and Toxicology and Industrial Medicine and Traumatic Surgery each with numerous subdivisions. Administrative functions with their application to the plant and individual worker are discussed. Health exposures and their engineering and medical control are treated in detail. Under the heading 'Industrial Medicine and Surgery' are discussions of placement of workers accidents occupational diseases, nonoccupational disability and workmen's compensation and rehabilitation.

The author makes no pretense of discussing the diagnosis and treatment of all occupational diseases but does deal at length with those which occur most frequently.

This is an accumulation of much of the best material which has been written on present day industrial health. As such it makes fairly complete general information on industrial health available in one volume. It should prove valuable in teaching the subject. The application of the procedures to small plants could have been given more emphasis.

Hemolytic Syndromes By William Dameshek M.D. Tibor J Greenwalt M.D. Russell J Tat M.D. and Camille Dreyfus M.D. A Reprint of an Exhibit Sponsored by the New England Medical Center Boston Mass. Presented at the 1942 Convention of the American Medical Assn. Atlantic City June 1942. Awarded Certificate of Merit for Correlation & Presentation of Facts. Paper Price \$1.50. No pagination. Boston 1942.

Physicians who have attended the annual sessions of the American Medical Association have often expressed a desire to have reprints of some of the meritorious scientific exhibits. This is a reprint of an exhibit on hemolytic syndromes presented at the 1942 session in Atlantic City. It consists of about forty charts diagrams and illustrations in loose-leaf form. Pertinent facts and theories concerning the physiology and pathology of blood destruction are presented in chart, diagram and outline form together with a brief review of the pathogenesis of hemolytic syndromes. The subjects of acute hemolytic anemia congenital hemolytic jaundice and familial nonhemolytic jaundice sickle cell anemia Mediterranean anemia, hemoglobinurias chronic hemolytic anemia Rh factor and erythroblastosis fetalis are also epitomized in diagrams illustrations and outline. Pertinent clinical and laboratory facts of the spleen and causes for its enlargement are presented in summary. Special procedures in studying hemolytic syndromes are indicated and a list of publications on pertinent hemolytic syndromes by the author and his workers are appended. The reprint of this exhibit material is most useful to physicians students and those interested in hematology. Much time and thought have obviously been taken in the preparation of this material, and the value of a reprint goes beyond that of a mnemonic. It is a provocative correlation of facts that should be stimulating to any student or medic.

Studien am menschlichen Sperma Von Charles A Joël Cloth Price 20 Swiss francs 12 marks Pp 154 with illustrations Basel Benno Schwabe & Co Verlag 1942

This interesting and compact book demonstrates that scientific research in Europe is not entirely devoted to the destruction of man. The text is elaborately written and excellently illustrated with various forms of sperm dyscrasias and morphology. A bibliography of 538 references accompanies the volume.

The first section of the book summarizes man's knowledge of the subject from the time of Leeuwenhoek. In speaking of the method of obtaining material the author stresses the fact that a week's continence should precede an examination of an ejaculate. The author makes it a practice to wait thirty minutes before examining a masturbated ejaculate in order to be sure that the sperm heads have had time to free themselves from the mucus. He stains all specimens with Ziehl's carbol fuchsin.

In the consideration of a diagnosis of necropermia the author cautions and goes to great length to show that although the spermatozoa may appear to be motionless they may not be dead. After the addition of isotonic solution of three chlorides isotonic dextrose, isotonic solution of sodium chloride or buffer solution, the heretofore motionless spermatozoa may begin to move again in twenty-four hours and be completely revived. The author finds that to revive motionless spermatozoa and cause activity it is best to use 8 parts of 5.42 dextrose to 2 parts of eighth normal magnesium chloride solution. He adds 10 parts of this mixture to 1 part of ejaculate. The spermatozoa if alive will revive and become active. After ten minutes if there is no activity he makes a diagnosis then, and only then of necropermia. This state of inactive but viable sperm he terms akinesis.

TABLE 3—Influence of Ferment Inhibitors on Motility of the Sperm

Ferment	Sperm	Sperm Plasma	Prostate	Seminal Vesicles
Cholinesterase	—	+	++	++
Monoamino-oxidase	—	++	++	++
Diamino-oxidase	—	++	+	+

In discussing morphology Joël rightly condemns Blass's heat fixation method because of the change or destruction of the cellular proteins which it causes. He considers supervital staining the method of choice in preparing specimens for microscopic examination.

Diamino-oxidase was first reported by Zeller in 1938 and it is identical with Best's histaminase and has a great deal to do with the sexual apparatus in man as well as in animals. Diamino-oxidase is found in the blood serum of pregnant women and in the liver of pregnant rats. It is also found in human spermatozoa, the human prostate, the semen and the seminal vesicles. When a ferment acts on polyamino-oxidase (spermedine) it breaks up into histamine, cadaverine, putrescine and agmatine during the process of which oxygen is absorbed. It is this absorption of oxygen that can be measured. The process of fertilization has some connection with the chemical diamino-oxidase. A test of the blood plasma during pregnancy shows increased quantities of diamino-oxidase.

The work of Belanochkin with inhibitors is mentioned and utilized. Some of these substances as potassium cyanide neutralize the substance diamino-oxidase. A rather detailed discussion of activators and inhibitors of spermatogenic activity is given. The results of the author's own research work presented in this volume are as follows:

- 1 The diamino-oxidase of human semen is present in the sperm plasma and not in the cellular elements.
- 2 Cholinesterase is also present only in the sperm plasma.
- 3 In the prostate there is very little diamino-oxidase but more of monoamino-oxidase and cholinesterase.
- 4 The seminal vesicles contain the same amount of monoamino-oxidase and diamino-oxidase as the prostate.
- 5 Carbonyl reactions (semicarbazide and dioxanone) inhibit in small concentration the motility of spermatozoa and activate them in greater concentrations.

This volume furnishes a fund of information which could be of considerable value to students, teachers and investigators on the subject as a work of reference.

Neurology By Roy R. Grinker, M.D., Chairman, The Department of Neuropsychiatry of the Michael Reese Hospital, Chicago. With the assistance of Norman A. Levy, M.D., Associate Neuropsychiatrist, Michael Reese Hospital, Chicago. With a chapter on Brain Tumors by Paul C. Bucy, M.D., Professor of Neurology and Neurological Surgery, University of Illinois College of Medicine, Chicago. Third edition. Hackett. Price \$6.50. Pp. 1136 with 116 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

This book was first published in 1933, and the revisions, reorganizations and additions of new material enhance the value of the volume. The author continues in his "attempt at a correlation of certain biological data which are considered of importance to the study of the human nervous system in health and in disease." The first section deals with general embryologic, anatomic, physiologic and pathologic considerations, which provide a suitable introduction to the clinicopathologic descriptions of the major portion. While this introduction offers a source of review for the student who has already studied similar material in the past, it is not in itself an adequate source of material for the student to whom it is newly presented. Less effort at encyclopedic completeness and more emphasis on clinicopathologic presentations would be more useful. The pathologic descriptions are sometimes vague and sketchy and apt to be confusing because of lack of correlation of the reports of the various investigators. The author's effort, however, to correlate structure and function is an admirable one and on the whole ably presented.

To the chapter on pathology have been added a few pages on chemistry, and about this the author pointedly remarks: "Confidence that biochemical research alone will solve the problem of mental disease without the aid of dynamic psychology is, however, not justified in the light of a broader point of view. It represents a displacement from the old narrow concept that the etiology of personality deviations will be discovered in cell changes visible under the microscope (Nissl) to a modernized version that it will be discovered in a test tube." The psychosomatic approach to problems formerly considered as almost wholly physical or chemical indicates the modern trend of etiologic approach.

In the course of a few pages the author has done remarkably well in summarizing our present knowledge of electroencephalography. Recent developments in neurophysiology and experimental neurology, including the newer observations on hypothalamic functions and corticohypothalamic relations, are adequately treated. The operation of prefrontal lobotomy as performed by Freeman and Watts is mentioned, but those authors would probably take exception to the statement that "the procedure is not recommended except as a last resort and is still in its experimental stage." The chapter on the extrapyramidal motor system is largely rewritten, Bucy's recent review of the neurologic mechanisms of athetosis and tremor being used as the nucleus of the exposition on extrapyramidal dysfunction. Too much emphasis is placed on the efficacy of the "Bulgarian cure" of parkinsonism. In the discussion of aphasia the author emphasizes the clinical formulations of Henry Head, but not enough detail of the technic of examination of the aphasic patient and of the interpretation of findings is given. The average medical student finds this a difficult subject to comprehend and is usually at a loss as to the methods of approach to the aphasic patient. The section on intracranial tumors is written by Paul C. Bucy and is a clear, succinct review of the subject and written in a style that is not too difficult for the initiate in neurology to understand.

Recent developments in clinical neurology, such as the use of the sulfonamides in therapy, the Sister Kenny treatment of poliomyelitis, St. Louis type of encephalitis, equine encephalomyelitis, Guillain-Barre syndrome, nutritional and vitamin deficiencies, herniated nucleus pulposus and the use of the electroencephalogram and arteriography in neurologic diagnosis are all discussed in an appropriate fashion for a textbook of this kind.

The illustrations are good and many new tables culled from the literature have been added, some good and others so detailed as to be confusing to the average student. The references are carefully selected and informative and the index is excellent. The book can be well recommended.

Sulfanilamidoterapia local Por el Doctor Juan Naslo. Facultad de Ciencias Médicas del Litoral. Paper. Pp. 150 with illustrations. Buenos Aires: Editorial Anacleto López, 1942.

The author outlines his own experiments in the Pharmacologic Institute of the Faculty of Medicine of the Litoral. At the same time he describes his research work in the clinics of the Rosario Hospital of Buenos Aires. The work deals with the sulfonamide compounds locally applied. The experimental section deals with all kinds of wounds, aseptic and septic, experimentally provoked. Some of them were infected with several strains of streptococci and staphylococci, with the addition in some instances of foreign bodies, and at times suturing and treating at different periods. The group of animals amounted to 185. Experimentally he made wounds, general and localized peritonitis, burns and fractures of all types. The clinical section deals with an enormous group of surgical diseases as well as with some localized lesions in the specialties of dermatovenereology, ophthalmology, odontology, otolaryngology and orthopedics. The number of patients treated is also extensive. All kinds of bacteriologic and bacteriologic controls were practiced. There is also a description of the effects of the drugs on each strain in vivo as well as in vitro, and the author succeeds in giving the reader a complete idea of how to treat each disease and how to use each sulfonamide drug.

American Agriculture, 1899-1939. A Study of Output, Employment and Productivity By Harold Barger and Hans H. Landsberg. National Bureau of Economic Research, Inc. Number 42. Cloth. Price \$3. Pp. 110 with 17 illustrations. New York: National Bureau of Economic Research, Inc., 1942.

In wartime the place of agriculture in the national economy has assumed unusually widespread interest. Discussions of our ability to function as a bread basket for the world are heard with increasing frequency on the radio, in the press and on the streets. For those who would attempt to evaluate the plethora of proposals which crop up, the present volume should prove highly valuable. The number of persons gainfully employed in agriculture appears to have remained substantially constant over the period studied, although farm production has gone up approximately 50 per cent. This trend in production barely keeps pace with the population growth, thus it may be seen that output per worker has risen. Compared with the increase in output of manufactured goods, which show an increase of some 400 per cent within the period studied, agriculture makes a poor showing. Publication of the present volume was made possible by investigations conducted by the National Bureau of Economic Research, Inc., under grants from the Maurice and Laura Falk Foundation of Pittsburgh.

Clinical Diagnosis by Laboratory Methods. A Working Manual of Clinical Pathology By James Campbell Todd, Ph.D., M.D., and Arthur Hawley Sanford, A.M., M.D., Professor of Clinical Pathology, University of Minnesota (The Mayo Foundation). Tenth edition. Cloth. Price \$6. Pp. 911 with 380 illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

During the last thirty-five years clinical pathology has undergone marvelous development. It is now a recognized specialty in medicine with some thousands of physicians who devote themselves exclusively to its practice. Each year new techniques are developed which throw still further burdens on the laboratory as the handmaiden of medical skill. An especially new phase is the use of the laboratory as a guide to therapy as occurs in the administration of the sulfonamides or vitamin K. The isolation of viruses, the classifications of Rickettsia, the determination of blood groups and the use of physical methods such as photometric technics are further examples of the great progress in this field. Moreover, new techniques are now submitted promptly to comparative studies and officially evaluated, as, for instance, the multiple serodiagnostic methods used in syphilis. All these techniques are described in this work. The present edition is, moreover, enriched with seventy-two new illustrations. Early in its career this book was accepted as a standard in its field. The intensive consideration given by the authors to maintaining its quality has made its utility still greater. The appendices, which deal with office laboratory methods and equipment, staining solutions, normal solution weights and measures and the laboratory findings in important diseases, add greatly to its practicality. The detailed index, occupying more than fifty pages, enables constant, ready use.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

EFFECTS OF MENSTRUATION, PREGNANCY AND ANESTHESIA ON PERMANENT WAVES

To the Editor—I would be interested in your opinion of the oft repeated claims by hairdressers that (1) permanent waves are not so successfully given to a pregnant person as to one not pregnant (2) permanent waves are not so successfully given within four weeks of an ether anesthetic as prior to the anesthetic and (3) permanent waves are not successfully given when the menses are present.

M D Colorado

ANSWER—Of the many explanations given by hairdressers for the failure of permanent wave manipulations, the three cited seem to be among the most reasonable. With regard to statements 1 and 3 it has been shown by Basler (*Menstruation und Haarwurzlefestigkeit, Med Klin* 35 1111 1930) by careful measurement of the pull needed to epilate hairs on the forearm and other parts of the skin that the force necessary varies during the menstrual cycle. Just before the flow is due the hair becomes more firmly fixed in the skin and a greater weight was necessary in Basler's apparatus in order to loosen it. As menstruation began the amount of weight needed decreased until at the end of the monthly period it was considerably lower than normal. After the menstrual flow ceased, the firmness with which the hair was fixed in the skin returned to normal. In 1 case the weight necessary to loosen the hair increased to 24 Gm just before the period, went down to 9 Gm at the end of the period and then soon returned to normal, a point between these two extremes. Basler attributes this weakening of the connection between the hair and the skin to the increased succulence of the skin during menstruation. If this change occurs also in the scalp as is reasonable to surmise, it takes little imagination to think that it may affect the way in which the hair responds to the manipulations intended to produce the permanent wave.

With regard to statement 2, one must consider in connection with any administration of ether the condition operation or parturition which called for anesthesia. It is known that such events may rarely be followed in the course of one or several months by a partial, usually temporary, alopecia. Whether caused by the operation or the anesthesia or both, it is possible that the hair in a much larger percentage of women may be affected by such disturbances so that it reacts badly to the efforts of the hairdresser.

Thus, while there is no definite proof of the claims made, meager knowledge of the changes in the skin and hair during menstruation and pregnancy and following parturition and surgical operations for which ether anesthesia was used seems to favor the possibility that such claims are correct.

HEALING OF FRACTURES IN OSTEITIS DEFORMANS

To the Editor—A patient aged 50 has a transverse fracture of the upper third of the left femur at the site of a previous fracture in 1937. Then as now he was suffering from osteitis deformans. The bone is now considerably deformed but reduction has been satisfactory. Will you please give me any suggestions you can to assist in getting firm union in this bone? His present reduction is being maintained by a plaster spica cast from the breast to the toes.

M D Ontario

ANSWER—As a rule fractures of patients who have osteitis deformans (Paget's disease) unite and in this case in which there is a transverse fracture of the upper third of the left femur chances are in favor of union being obtained. Care should be taken to keep the leg held quiet sufficiently long and in proper position to make certain that union is present before weight bearing is permitted. The usual indications of firm union are lack of tenderness and pain on pressure at the site of fracture and bony trabeculations crossing the line of fracture in the x-ray films. Every effort should be made to insure this union as bone grafting is not as successful in this type of case as in normal conditions.

VARIATIONS IN ORAL TEMPERATURES AND TUBERCULOSIS

To the Editor—Like most physicians who have practiced only in hospitals I have seldom had occasion to deal with the practical aspects of recording oral temperatures. During the past few months however while convalescing at home from a small pulmonary tuberculous lesion I have naturally made numerous recordings of my own temperature and have found that the matter is somewhat more complicated than I had heretofore suspected. Using three different apparently accurate thermometers I have found that the maximum reading is never reached until after the lapse of at least six minutes and often only after the lapse of ten to twelve minutes. This occurs if the thermometer has not been used for several hours. If on the other hand the mercury is shaken down after a recording and the temperature immediately taken a second time, the previous maximum reading will be reached in two minutes or less. (The practical implication of the latter observation is that if the same thermometer should be used on a number of patients in succession and recordings made at the end of the customary three minute period, only the temperatures of the second and succeeding patients would be true maximums.) A typical series of readings would be 94.0 F (initial reading) 98.3 F (three minutes) 98.5 F (five minutes) 99.2 F (ten minutes) and 99.3 F (twelve minutes). In a second recording taken immediately afterward the maximum of 99.3 F would be reached in two and one-half minutes. I have been particularly careful in making these observations not to cause any friction between my tongue and the bulb of the thermometer. I fully appreciate that when dealing with temperatures of 100 F and over this situation may not obtain, or if it does it is of no consequence. I do feel however that it is of the utmost importance to know whether a patient's true temperature is 98.4 F or 99.3 F particularly when the diagnosis or the state of activity of such a disease as tuberculosis is involved. If my own temperature had been taken during the past few months in the conventional manner that is using a three or even a five minute period it would have been recorded invariably as 98.6 F or below whereas after twelve minutes it has been almost invariably between 98.9 F and 99.3 F usually at 99.0 F. The higher value is of course the one which would have been recorded had my temperature been taken with a thermometer that had been used immediately before on other patients. These minute variations would seem for less important to me if it were not for the fact that this questionable low grade fever is the only objective sign of possible activity of my tuberculous process now present other than a pulse rate varying between 80 and 96. At least six competent radiologists and phthisiologists have declared that I have shown no evidence of activity for a number of months their almost unanimous opinion is that I can now begin a normal mode of life. One has taken the extreme view that my apical shadow represents a pleuritis rather than a parenchymal lesion and that my initial symptoms were probably due to a bronchitis rather than to a tuberculous process. All these men I am certain would attach great significance to my temperature range if it occurred after the usual three or five minute period but when I inform them that it occurs only after ten to twelve minutes they are inclined to dismiss it as of no importance. It is of added interest that during the five months I spent in the hospital my temperature after the third day was never recorded on the chart as being above 98.6 F during the same period my own unofficial readings were frequently above 99.0 F provided I kept the thermometer in my mouth several minutes longer than the nurse was accustomed to do. Will you kindly furnish me with an opinion of the possible significance of these slight elevations as well as with any appropriate references to the literature?

M D Massachusetts

ANSWER—The temperature of various organs or the body differs from time to time, depending on such factors as activity. Obviously, thermometer readings from the axilla, the mouth or the rectum are not true body temperature. Nevertheless rectal and oral temperatures serve the usual clinical purpose of determining whether significant fever is present. Oral temperature recordings are influenced to a considerable degree by the atmospheric temperature. There are numerous causes of so-called slight elevations due to nervousness, activities of the digestive system or general body activities. Persons with active tuberculosis have reported temperature readings of a half degree higher on one side of the mouth than the other. This probably is due to the same phenomenon as results in the so-called hectic flush of one cheek or the burning sensation of a given part of the body such as the lobe of one ear or the chest wall. This phenomenon has been explained on the reflex basis. When the sensory fibers of the trigeminal nerve are stimulated dilatation of the vessels occurs in the areas which these fibers supply. The irritation produced by disease in the lung results in stimuli which pass over the afferent fibers of the vagus nerve. In the trigeminal nerve there are dilator fibers of cerebral origin. Thus the impulses carried over the vagus nerve from the area of the disease pass reflexly over the trigeminal nerve and result in dilatation of the blood vessels.

The 98.6 F which is generally considered as the normal oral temperature is really an average and was determined by taking the temperatures of large numbers of persons apparently in good health. Many were below and many were above this level. Some individuals who are in excellent health have normal oral temperatures of or slightly above 99 F.

The observation made with reference to the increased time temperature recording after having the thermometer in the mouth much longer than the usual time has been made by many

It is usually due to the fact that when the mouth is kept closed for several minutes the temperature rises because of the absence of influence of the atmospheric temperature and in time closely approximates the rectal temperature. On the same basis one may explain the fact that when the thermometer is removed and the mercury is quickly shaken down and is immediately replaced there is little opportunity for the mouth temperature to be reduced by the atmospheric temperature. Most clinicians agree that a mouth temperature of 99 F or even slightly higher is well within normal limits when the thermometer is retained in the mouth from five to ten minutes, and therefore this is no indication whatever of the activity of a tuberculous process. If there is no other evidence of active tuberculosis the temperature readings mentioned should not be considered significant.

LENGTH OF STORAGE IN "DEEP FREEZE" COMPARTMENT

To the Editor—As a direct result of wartime economy and probably to be carried into the peace which follows, foods are being stored in "deep freeze" compartments at temperatures from 10 to 20 degrees below zero. The idea, of course, is that these foods can be kept at these temperatures indefinitely. To all appearance, meats and vegetables taken out of these compartments at any time are absolutely fresh and in excellent condition. However, most sales pamphlets which advertise these "deep freezers" claim that fish should not be kept more than four months and meat more than eight months. Fish, so it is claimed, undergoes a chemical change which takes place in storage. As a result of these suggestions, much meat and fish throughout the country is thrown away at the end of this period in order to avoid the "poisoning" effect which supposedly sets in. I think this idea should either be confirmed or emphatically denied on the basis of facts. My own thought is that at the low temperature which is created in these compartments, animation is completely suspended and that no chemical deterioration takes place.

Paul Lahvis, M D, Gowanda, N Y

ANSWER—There are no changes in properly prepared frozen and stored fruits, vegetables or meats which develop poisonous products during frozen storage. Fish, after several years' storage, might be indigestible or unpalatable but not poisonous.

Quality deterioration on prolonged storage does occur and is faster at 5 and 10 F than at 0 and -10 F. Deterioration, chiefly the development of rancidity, is more pronounced with fatty or oily products such as fish or pork and is accelerated by widely fluctuating storage temperatures and faulty packaging.

Because of this deterioration in quality and for economic reasons, producers of frozen foods try to move their products within a reasonable period of time, usually four to six months for pork and eight to ten months for most meats. Foods which are held longer than this do not develop harmful properties, and often the deterioration is so slight that only an expert can detect the change. Discarding good meat or fish is wasteful practice and should be strongly condemned.

SULFATHIAZOLE OINTMENT FOR THE EYE

To the Editor—I am convinced after repeated observations on patients that the sulfathiazole ointment or cream such as is flooding the world's market today is harmful to the eye when introduced into the conjunctival cul-de-sac. One application produces sufficient annoyance to convince me that it is not a harmless agent. Many applications and rubbing produce a keratoconjunctivitis not unlike the virus conjunctivitis of the West Coast. Any one may readily elicit this experience if he will place a small amount of the grease in the eye, and there is ample evidence that this drug acts as an escharotic. T J Dimitry, M D, New Orleans

ANSWER—There are three types of inflammation from sulfathiazole ointment in the eye which can be readily defined. The first is a typical allergic reaction with dermatitis of the eyelids which disappears without residual effects as soon as the drug is discontinued. The second is a conjunctival inflammation produced by an irritating base such as the vanishing cream base occasionally used in preparations designed for the skin only. The third is a mild traumatic reaction from improperly prepared ointment containing large crystals. The suggestion that sulfathiazole ointment as prepared for eye use acts as an escharotic is false. This also applies to the statement that many applications produce a keratoconjunctivitis like the epidemic keratoconjunctivitis of the West Coast. As with the other sulfonamides, sulfathiazole ointment is being used indiscriminately and unnecessarily in many cases, but the only apparent danger from this is the sensitization of certain individuals so that the drug cannot be used by mouth when indicated by pneumonia or other serious illness. These cases of sensitization are rare, however. Damage to the eye resulting from the use of sulfathiazole ointment has not been observed in an extensive experience with the local use of this drug. It would be well to have commercial preparations labeled carefully so that ointment bases designed only for cutaneous use would not be employed in the eye. The correspondent may have been using one of the cutaneous preparations.

ALLERGY TO CERTAIN FOODS DEVELOPED AFTER APPENDECTOMY

To the Editor—In November 1942 I had an appendectomy. Three weeks later I suddenly began to have angioneurotic edema. This has persisted, involving various parts of my body. I had a number of intradermal tests, but most of the reactions were negative. However, by means of elimination diets I have found that I am sensitive to wheat, chocolate, eggs, bananas and milk. What puzzles me is the reason for this. In the past I occasionally would have a hive or two following ingestion of eggs. I also have had dust allergy but never angioneurotic edema. In the way of therapy I find that if I watch my diet I am symptom free. I have tried histamine, histaminase and calcium, but the allergy persists. I might mention that my father-in-law, who underwent an appendectomy one week prior to me, has hives on eating fish. He never had before. Can you explain this phenomenon?

M D, Pennsylvania

ANSWER—No one can say why angioneurotic edema suddenly develops in certain individuals. It is undoubtedly due to sensitivity to certain foods or drugs. It frequently happens, however, that sudden overindulgence in a food will bring on symptoms which would not have occurred had the food been eaten in moderate amounts. Quinine is one of the most common causes, but other drugs may be responsible. As this patient has learned by means of elimination diets that he is sensitive to wheat, eggs, chocolate, bananas and milk and has no symptoms when he avoids these, it would be wise to continue avoiding them for a month or two. The foods should then be tried one at a time in fairly large quantities and at intervals of a week or two. In testing, it would be wise to try the food in a cooked form rather than in a raw state. If no symptoms occur from boiled milk, for example, then raw milk can be tried. Recipes for wheat free foods may be obtained from the Ralston Purina Company.

IRRADIATION FOR CANCER IN PRESENCE OF TUBERCULOSIS

To the Editor—Is active pulmonary tuberculosis a contraindication to the use of high voltage roentgen irradiation for (1) cancer of the lung or (2) cancer in other organs of the body?

Nathan Sedofsky, M D, Olean, N Y

ANSWER—1 Since cancer of the lung is not curable by radiotherapy and since the palliative help which can be expected is distinctly limited, one should hesitate to irradiate a carcinoma of the lung in the presence of active pulmonary tuberculosis. The chances of harming the patient under these circumstances would seem to be greater than any hope of benefit.

2 Whether to irradiate cancer in another organ of the body depends both on the site of the cancer and on the chances of cure or prolonged palliation under the special circumstances that are encountered. Obviously, one must weigh the chances of improving the neoplastic condition against the chances of causing harm to the active pulmonary lesion.

DIETHYLSTILBESTROL

To the Editor—I read with interest the question and answer in *The Journal*, May 22, 1943, entitled "Contraindications for Diethylstilbestrol." I was especially interested in some of the contraindications, such as excessive menstrual flow and prolonged menstrual flow. It has been discovered that diethylstilbestrol is the most efficient drug yet for the treatment of the two conditions (Karnaky, K J. *South M J* 3:2 813 [Aug] 1939, 3:3 1045, 1285 [Dec] 1940, 3:5 838 [Sept] 1942, *Texas State J Med* 36 379 [Sept] 1940, *J Nat M A* 3:2 235 [Nov] 1940, *M Times* 60 199 [May] 1941, *Am J Obst & Gynec* 43 385 [March] 1942, McGinn, E J. *J Clin Endocrinol* 2 302 [May] 1942, Cuyler, W K, Hamblen, E C, and Davis, C D, *ibid* 2 438 [July] 1942). It has been found in the Jefferson Davis Hospital, Department of Obstetrics and Gynecology, Research Division, that diethylstilbestrol will stop uterine bleeding quicker than the time it takes to get the patient to the hospital, prepare the patient for and then perform the dilation and curettage of the uterus. For uterine bleeding with or without fibroids, give five 5 mg diethylstilbestrol (plain) tablets by mouth and follow with two to three 5 mg tablets every fifteen minutes until the bleeding stops. Then give one 5 mg tablet every night for thirty nights, plus desiccated thyroid to tolerance dose and one lipoiodine tablet every morning for sixty mornings. In cases of excessive menstrual flow and all menstrual disorders due to an endocrine cause or causes whether it is spotting, amenorrhea or flooding the treatment is the same. After the uterine bleeding stops, the uterus can be examined by taking an endometrial biopsy under a general anesthetic and the tissue examined for signs of malignancy. If the patient continues taking diethylstilbestrol she will become tolerant to the drug in five to six days. If she becomes too nauseated she can insert one 1 gram penitrol sodium rectal suppository every three to four hours. I have been unable to find any harm from diethylstilbestrol after giving it to 3,227 patients during the past five years. It did not stimulate malignant cells.

THE SACRO-ILIAC JOINT AND PAIN OF SCIATIC RADIATION

CHARLES D. HERSHEY, MD

ANN ARBOR, MICH

The cause of pain of sciatic radiation has long been a subject of investigation, and the causative factors advanced for this condition are legion. My interest was drawn to the role of the sacro-iliac joint in its relation to the components of the sacral plexus by the high incidence in anatomic specimens of hypertrophic arthritic changes with spur formation in the region of the anterior surface of the joint particularly in the area traversed by the lumbosacral trunk. It is my purpose in this paper to present the anatomy of this region and the data relating to the arthritic changes in the sacro-iliac joint as determined by dissections on 64 cadavers.

The involvement of the lumbosacral trunk by disease of the sacro-iliac joint due to their close anatomic relationship was first demonstrated in 1861 by John Hilton¹ in his lectures to the Royal College of Surgeons at which time he presented a clinical case which he ascribed to this condition. In 1905 Goldthwait and Osgood² discussed arthritis of the sacro-iliac joint both its atrophic and its hypertrophic forms, the latter being in their opinion, far more common. These authors believed that the referred pains in this condition were "undoubtedly due to pressure of the hypertrophic tissue upon the lumbosacral cord as it passes over the articulation." Albee³ in 1909 dissected the sacro-iliac region of 50 specimens and concluded that the proximity of the lumbosacral trunk to the joint in its lower one third explained the presence of persistent pain in the distribution of the sciatic nerve. In 1925 Dantorth and Wilson⁴ described the anatomy of the region as observed in 12 cadavers. They believed that nerve pain due to joint disturbance might be produced at the point at which the fourth and fifth lumbar nerves cross the sacro-iliac joint at its lower margin, although it was their opinion that such involvement is more likely to take place in the lumbosacral region owing to the enclosure of the nerves in the bony intervertebral foramina. Yeoman⁵ in 1928 presented 100 clinical cases

of sciatica, 36 per cent of which he attributed to arthritis of the sacro-iliac joint as demonstrated by roentgenograms of the joint. However, he described the piriformis muscle as lying between the lumbosacral trunk and the joint at its lower margin and attributed sciatica as being produced in these cases by a periarthritis involving the anterior sacro-iliac ligament and piriformis muscle and the latter involvement in turn affecting the sciatic nerve. This anatomic relationship was not found in any of the dissections in the present study, as will be discussed later. In 1930 Sashin,⁶ basing his work on 257 postmortem examinations in which both sacro-iliac joints were removed, emphasized that nothing except the thin anterior portion of the joint capsule intervenes between the lumbosacral trunk and the joint space. Reviewing 1,559 human skeletons in the Hamann

Fig 1.—Diagram of pelvis showing formation of sacral plexus with lumbosacral trunk passing over lower sacro-iliac joint.

Museum of Anthropology, Willis⁷ in 1933 noted the high incidence of bone changes in the sacro-iliac joint. In 1934 Freiberg and Vinke⁸ referred to Yeoman's work and emphasized his description of the piriformis muscle lying between the lumbosacral trunk and the joint. They believed that the irritated piriformis was responsible for sciatica in some instances and based their opinion on their dissections on 14 cadavers. Casuccio⁹ in 1938 studying 16 unembalmed bodies affirmed the direct and constant relationship of the lumbosacral trunk to the sacro-iliac joint.

Dr. Rollo E. McCotter, professor of anatomy, assisted the author in this study.

ANATOMY

As illustrated in figure 1, the anterior portion of the sacro-iliac joint produces a curving line which swings most lateralward in the region of the ala of the sacrum and then passes downward and medially at its lowermost end. The joint is covered anteriorly by the

inferior gluteal vessels pass between the second and the third sacral nerve to reach the thigh through the infrapiriformic space.

COMMENT

In the present study the anterior sacro-iliac regions of 64 embalmed bodies were dissected. The relationship of the lumbosacral trunk to the sacro-iliac joint was determined in all specimens and the degree of arthritic lipping of the joint was noted and classified as to severity. In all specimens the lumbosacral trunk crossed the lower one third of the sacro-iliac joint and lay directly on the joint.

The observations relative to the arthritic changes in the joint are contained in table 1. It appears significant that 25 per cent of the bodies examined showed well defined lipping of the joint anteriorly. In many of these the joint line was extremely rough and jagged and in most of the cases the lumbosacral trunk was pushed forward and was forced to angulate over this process, as shown in figures 2 and 3. Indeed in at least 2 of the specimens there was an actual groove in the posterior surface of the trunk at the point at which it was in contact with the joint. Sashin suggested that such a process might affect the nerve not only by direct pressure but also by osteophytes extending into the nerve itself.

The fact that 13 of the cases showed no spur formation does not necessarily exclude arthritis of the joint but merely excludes arthritis of the hypertrophic type which might affect the adjacent structures by direct bony extension. Indeed Sashin in a series of 257 post-mortem examinations found arthritic changes in all

FIG. 2—Appearance of dissection of pelvis, showing lumbosacral trunk forced to angulate over hypertrophic lipping of lower one third of sacro-iliac joint.

anterior sacro-iliac ligament, which is a very thin structure of little strength. It is through this weak anterior capsule that exudate breaks in suppurative sacro-iliac joint disease.

The sciatic nerve is formed by the fourth and fifth lumbar and first, second and third sacral nerves. The fourth lumbar nerve splits into a larger upper segment which contributes to the lumbar plexus and a smaller lower segment which passes downward to unite with the fifth lumbar nerve over the ala of the sacrum. This point of union is not constant and may occur at a slightly higher or lower level. The nerve trunk thus formed is the lumbosacral trunk, which courses downward, lying on the anterior surface of the sacrum just medial to the sacro-iliac joint until the lower one third of that articulation is reached, where the joint line passes medially. There the lumbosacral trunk crosses the joint and lies directly on the capsule. In very broad pelvises the trunk may remain medial to the joint, but this was not seen in any of the 64 bodies examined. Although the piriformis may have a few fibers of origin from the very lowermost portion of the capsule of the sacro-iliac joint, it always occupied a medial position to the lumbosacral trunk at the level at which the latter traversed the joint in all of our specimens.

The first, second and third sacral nerves pass laterally from their respective foramina anterior to the piriformis and unite with the lumbosacral trunk to form the sacral plexus. The hypogastric vessels lie anteriorly to the sacral plexus with the superior gluteal vessels passing between the trunk and the first sacral nerve (fig 2) to leave the pelvis through the suprapiriformic space. The

FIG. 3—Lipping of sacro-iliac joint pushing lumbosacral trunk forward. All hypogastric vessels with the exception of the superior gluteal artery have been removed.

sacro-iliac joints in persons over the age of 60. Although hypertrophic changes were not found in 7 of the bodies over the age of 65 in the present investigation (table 2), this does not rule out degenerative changes in these joints.

On the whole, those showing moderate involvement were not considered as apt to produce any considerable

effect on the trunk. Willis describes two types of osteogenic change in the sacro-iliac joint (1) a smooth calcification of the anterior sacro-iliac ligament and (2) an irregular lipping at the periphery of the joint. The minimal cases in the present study would fall in this first group, as we placed all joints with a small

As only 10 of the specimens were from females, no significant comparison could be made as to sex distribution of this condition. Willis found sacro-iliac ankylosis to be 3 times as frequent in the male as in the female. Saslin concludes that in men the process starts earlier and proceeds faster and with greater intensity than in women. Willis found that the incidence of sacro-iliac ankylosis was twice as great in Negro as in white subjects.

This spur formation is demonstrable by x-ray as is shown in figure 5, which is a roentgenogram of a dissected pelvis known to have a 3 plus lipping. In order to demonstrate the point on the joint over which the lumbosacral trunk passes, it is necessary to alter slightly the routine technic of pelvic roentgenography. It is necessary that the x-ray tube be placed at a so-called negative angle of approximately 20 degrees, i. e., with the tube at 20 degrees from the perpendicular and toward the head. The usual technic outlines the joint a short distance below the point in question.

CONCLUSIONS

1 The lumbosacral trunk was in direct contact with the sacro-iliac joint at the point at which it traverses the joint in its lower one third in all of the 64 specimens studied.

2 The upper portion of the origin of the pyriformis muscle was found to lie medial to the lumbosacral trunk in this study and never to lie between the trunk and the joint.

3 Hypertrophic arthritis in the form of severe spur formation on the anterior line of the sacro-iliac joint

Fig. 4—Hypertrophic spur formation involving only the middle one third of the sacro-iliac joint. The lumbosacral trunk lies medial to the spur and would be unaffected by it.

degree of smooth elevation of the anterior joint line in this classification. These cases could not conceivably produce sciatic pain by direct pressure on the nerve.

Casuccio in studying 65 patients with sacro-iliac joint disease found that 46 per cent had sciatica. He pointed out that the reason that this percentage is not higher is that the joint line is long and the diseased portion may not be in contact with the trunk. That well defined spurring of the joint may not encroach on the lumbosacral trunk at all is illustrated in figure 4, in which the

60-94	7	5	4	7	23

hypertrophic change is limited to the middle one third of the joint and therefore lies lateral to the trunk. The lower one third of the joint must be involved in the arthritic process if the lumbosacral trunk is to be affected.

In the main the hypertrophic changes were found to be more pronounced in the older age groups as has been shown by Saslin and others. It is not by any means confined to persons of advanced age, however, as one of the specimens in this study showing very pronounced spur formation was that of a man of 35.

Fig. 5—X-ray appearance of dissected hemipelvis. Arrow points to spur formation in lower one third of the sacro-iliac joint at the exact point at which the lumbosacral trunk crosses the joint.

was found to be present in 25 per cent of the bodies that were studied. Most of these were considered capable of producing direct irritation of the lumbosacral trunk.

4 Hypertrophic sacro-iliac arthritis is more frequently found in the older age groups but is often encountered in younger persons

5 Hypertrophic tipping of the joint in its lower one third where the lumbosacral trunk crosses it can readily be determined by anteroposterior roentgenograms of the pelvis

THE TREATMENT OF EARLY SYPHILIS

BY THE CONCURRENT ADMINISTRATION OF
ARSENIC AND BISMUTH IN A PERIOD
OF FIVE DAYS

HERBERT RATNER, MD
CHICAGO

The five day treatment of early syphilis warrants special consideration at this time, for it has certain undeniable advantages. It apparently "cures" a majority of patients, it affords rapid control of infectiousness, it gives no opportunity for lapse in treatment and there is a considerable saving to the patient in both time and expense. An effective "speed-up" method of treatment is desirable at this time, for it may be anticipated from statistics of past wars and the experience of England in the last year that there will be a sharp increase in syphilis. The question of the safety of the method has been the greatest drawback to its general adoption, for the incidence of cerebral reactions, some fatal, far exceeds the recorded incidence of similar reactions from standard treatment. Proponents of the five day method suggest, however, that the reports of fatalities from conventional treatment are not a true reflection of their actual incidence, and furthermore that the risk involved with the rapid method is far outweighed by the serious late complications of syphilis which result from inadequate standard treatment.

At the Cook County Hospital the five day method was instituted as a clinical experiment to corroborate the promising results of Chargin, Hyman and Leifer.¹ From August 1940 to January 1943, 481 cases were studied. The therapeutic results thus far have been encouraging. There were no fatalities in the group, although there were 3 instances of cerebral reactions.

In the beginning of the study mapharsen was the sole drug employed and it was administered by continuous intravenous drip. At the end of the first year our statistics indicated failures from one course of such treatment in approximately 12 to 15 per cent of the cases. In the hope of reducing this percentage of failures, the technic was then modified so that a bismuth compound was administered in addition to the mapharsen, daily intramuscular injections of soluble bismuth being employed in order to retain the "five day" feature of the treatment.

Though the interval is perhaps too short to permit a conclusive statement, it appears that the incidence of failures from one course of treatment has thereby been reduced from 15 per cent to approximately 4 per cent. The earlier failures, it was noted, occurred almost

entirely in persons who had reported relatively late with eruptions of secondary syphilis. At first, therefore, bismuth was administered only to those with eruptions of secondary syphilis, but it was soon apparent that the bismuth was well tolerated, there being no increase in untoward symptoms. The concurrent use of arsenic and bismuth was then established as routine for all cases of early syphilis. It is of interest that Clausen, Longley and Tatum² later presented evidence from experiments with animals which indicated that the therapeutic effects from combining arsenic and bismuth were enhanced, "additive" to use Tatum's expression, and the combination caused no increase in toxic effects.

CLINICAL MATERIAL

The entire group numbered 481 patients, two thirds of whom were Negroes. There were 265 men and 216 women, 28 of them pregnant. With the exception of 12 cases of early syphilis, 1 congenital case and 1 of tertiary syphilis affecting the eye, every patient presented either a dark field positive chancre or an eruption of secondary syphilis. The oldest patient was a man of 48 and the youngest a girl of 14, the majority were in the early twenties.

TECHNIC

Before treatment the physical status of each patient was determined with the help of laboratory studies which included blood serologic tests, particularly the Kahn quantitative test, a complete blood count, urinalysis including tests for urobilinogen, icterus index, blood chemical determinations and a roentgenogram of the heart. The test for urobilinogen was found to be a most valuable procedure as an indication of the "course of events," and it became a rigid rule never to begin treatment until the morning specimen of urine had been tested for the presence of urobilinogen.

The daily dose of arsenic, regardless of age, weight or sex of the patient, was 0.24 Gm of mapharsen dissolved in 2,000 cc of 5 per cent dextrose solution. The supply for the entire day was made up in the morning and, with the solution maintained at room temperature, it was administered intravenously by the drip method for a period of about eight hours. A vein on the dorsum of the hand or one on the outer surface of the forearm near the wrist was selected in order to permit free motion of the elbow. The arms were alternated each day. The needles employed were the number 20 deep injection type, 1½ inches long. They were inserted up to the hub and then transfixed to the skin with adhesive tape. In addition, soluble bismuth sodium tartrate was injected intramuscularly into the buttocks in an amount equivalent to 22 mg of bismuth each day for the five days.

The patients required no special preparations before treatment. On the first day solid food was withheld to alleviate nausea, but thereafter the patients received the ordinary ward diet. After completion of the day's treatment they were permitted to be up and about.

On the sixth day the blood was again examined serologically and also the spinal fluid. The patients were discharged from the hospital the following day and instructed to return at monthly intervals for examination, particularly for serologic studies by the quantitative method. The clinical application of the

quantitative test is a relatively recent advance which has proved invaluable as a therapeutic index, not only by frequent observations of the progressive rise or fall of the serum titer of a patient's blood can one make an intelligent appraisal of his serologic status—whether serostast, improving or relapsing.

UNTOWARD SYMPTOMS AND REACTIONS

The reactions in general though troublesome, were of a minor nature. The most common complications were fever, muscle and pain up to the arm, which were usually most annoying on the first day of treatment. The pain occurred in about 60 per cent of the patients, nausea and vomiting in 75 per cent and fever in 45 per cent. These symptoms usually appeared during the fourth hour of treatment and continued for one day only but in a few instances they recurred on each of the five days. A secondary fever on the sixth day occurred in 30 per cent of the cases and lasted at most for a period of but three days. In addition our statistics indicated the incidence of mild headache in 25 per cent of the cases, restlessness in 4 per cent, 3 cases of precordial oppression,³ which was instantly relieved by the administration of atropine, transitory albuminuria in 5 per cent of the cases, cutaneous Herxheimer reaction in 4 per cent, 1 case of erythema multiforme on the second day, 1 of follicular purpura on the seventh day and several cases of morbilliform eruption, none of which necessitated interruption of treatment. Slight numbness and tingling of the hands and feet developed in 5 per cent of the cases in the second week after treatment and persisted for two or three weeks thereafter. It constituted a bothersome complaint in only 1 instance that of a woman treated during the third month of pregnancy.

Serious reactions did occur however in 4 Negro men who had received treatment with mapharsen only.⁴ In 2 of them there developed encephalopathy with transitory hemiparesis after treatment had been completed on the sixth day in 1 case, on the ninth in the other. A third patient experienced a single convulsion after three days of treatment, and the fourth patient on the completion of the first day of treatment during which he had received only 0.24 Gm of mapharsen suffered an overwhelming reaction with acute glomerulonephritis, anuria, uremia, hepatitis and pericarditis.⁵ All 4 of these patients recovered with no apparent sequelae and in each case there was a serologic reversal of the blood.

Aside from these 4 cases with serious reactions treatment had to be discontinued in 21 other instances because of the development of disturbing symptoms. Among them were 3 cases in which albuminuria developed apparently from a brand of bismuth that was soon discarded, 1 case of phlebitis, 8 cases of persistent fever of more than 101.4 F, and 9 cases in which treatment was suspended because of symptoms such as disorientation, drowsiness, crying spells, muscular aches, weakness and fainting. In all treatment was discontinued in 65 per cent of the cases because of the development of various reactions. All these cases

occurred early in the course of the study when caution and apprehension influenced the interpretation of symptoms. As the study developed the number of cases in which treatment had to be discontinued became considerably smaller. The incidence and severity of nausea and vomiting were decreased by withholding solid food on the first day, and the administration of 15 minims (1 cc) of essence of peppermint every four hours afforded quick relief to many patients. The free use of sedation with a mixture of chloral hydrate 15 grains (1 Gm) and sodium bromide 30 grains (2 Gm) every four hours was also effective in the more bothersome cases, and it seemed too to lessen the severity of the arm pain. The most beneficial single measure, however, was the inflexible rule to 'Discontinue therapy for the day on the development of any of the following: increasingly severe headache, pernicious nausea, repeated vomiting, undue restlessness, change in personality, temperature of 101.4 F or any other unusual symptoms. Immediately administer 200 to 400 cc of 25 per cent sucrose intravenously. If the symptoms persist follow with 2,000 cc of 10 per cent dextrose intravenously, this in turn to be followed by 2,000 cc of isotonic dextrose and saline solution subcutaneously. If on the following day the symptoms have not completely disappeared, again administer 200 cc of 25 per cent sucrose intravenously prior to the administration of mapharsen.' In cases in which treatment had to be interrupted temporarily, that day's unused mapharsen was then added to and distributed evenly over the course of the remaining days of treatment.

The immediate discontinuation of the therapy for the day on the development of such reactions and the free use of sucrose intravenously have undoubtedly been the most important factors in reducing the incidence of serious reactions, particularly the ominous cerebral reactions.

Exfoliative dermatitis, nitritoid reactions or blood dyscrasias did not occur in our series nor was there a case of liver damage except for the one unusual case which properly should not be charged against the five day technique. And most important there were no fatalities.

RESULTS

Early Syphilis—The series of cases studied totaled 481. Of this number 421 completed the full course of five day treatment, 310 of them with mapharsen alone and 111 with the combination of mapharsen and bismuth. Of the 60 patients who did not receive the full treatment 3 per cent were rejected after preliminary examinations on medical grounds, 65 per cent reacted unfavorably to the treatment and in the remainder treatment was withheld or suspended for nonmedical reasons and have no bearing on the study.

In the group of 310 cases which were treated with a single course of mapharsen alone 200 were observed for a period of five months or longer. One hundred and forty-nine of them became seronegative and 23 were progressing satisfactorily as shown by steadily decreasing serologic titers. Nineteen of the 200 cases resulted in serologic relapse in 3 others which were listed as cases with an unsatisfactory result there was a question as to whether they represented remissions, there was also 1 case of serologic relapse, and in the

⁶ The "discontinuation" technique was suggested by the excellent work of Lieut. Alfred B. Falk, M. C., A. U. S.

remaining 5 cases the results were still pending. In summarizing, to date, one course of five day treatment for early syphilis with arsenic alone gave results that were satisfactory in 86 per cent of the cases, failures in approximately 11.5 per cent, and the results were still pending in 2.5 per cent.

Of the group of 111 cases treated with one course of mapharsen and bismuth used concurrently, 35 were not evaluated because of a too brief period of observation. Of the remaining 76 cases, 50 became serologically negative, 21 showed progressive serologic improvement and there was 1 case of serologic relapse. The outcome in 4 others is still questionable and in the interest of conservatism they were listed as failures. Thus, to date, satisfactory results were obtained in 93.5 per cent of the cases and failures in 6.5 per cent of those who received one course of treatment with the combination of arsenic and bismuth. Further study of the questionable cases, we have reason to believe, will show this estimate to be too conservative.

Pregnancy^{6a}—Twenty-seven pregnant women received the treatment, 4 of them for primary syphilis, 15 for eruptions of secondary syphilis and 8 for latent syphilis of less than four years' duration. Ten received arsenic alone and 17 had the combined treatment. Twenty-six cases resulted in the birth of a full term, normal infant, 1 syphilitic infant was born of a mother who, after responding successfully to one course of treatment, acquired a second infection while the infant was still in utero. In addition, there were 5 women who had been treated for early syphilis by the five day method who subsequently became pregnant and, though no additional treatment was given, each has since given birth to a normal infant, in 1 case twenty months after completion of the five day treatment.

Retreated Cases—Twenty-three patients were retreated because of relapse, reinfection or serofastness. In none of them was there an allergic reaction or any other complication due to the second course of treatment. Eight of this group attained seronegativity, 9 cases showed satisfactory serologic improvement, 3 were still pending, although the serologic titer was showing a progressive fall, 1 case was lost from observation. From the very beginning of the study difficulty was encountered in deciding whether certain cases were examples of relapse or reinfection. The practice at first was to classify them all as failures, a practice which Schoch has criticized as being unwarrantedly conservative. None of the cases fulfilled the established criteria for reinfection, yet in many of them certain factors weighed the scale of evidence in favor of reinfection. There was, for example, the instance of a woman who received the five day treatment for an eruption of secondary syphilis. No primary lesion was observed by us. She became serologically negative and gave repeated negative tests for a period of four months. She then disappeared from observation and four months later returned with a chancre on her lip. She insisted, and she was not unintelligent, that there previously had not been a sore on her lip and it was the opinion of the entire staff that, despite the lack of established criteria, this case represented one of reinfection.^{6b} It

was soon noted that several other cases presented similarly doubtful circumstances, and, finally after careful weighing of the facts in each instance, the label of reinfection was given to 15 cases. All of them, after attaining seronegativity, gave repeated seronegative tests for several months. Each of them then presented new clinical evidence of early syphilis and a history very strongly suggestive of a new infection. Furthermore, although we have no tangible evidence for it, we are inclined to agree with Schoch, who has stated that in patients who have received rapid treatment "infection can take place in the face of reagin still remaining from the first infection".⁷

Additional Notes—The spinal fluid was examined in 420 cases. Slight abnormalities in the colloidal gold curve were noted in 10 cases, and in 12 cases there was an insignificant increase in the cell count. The spinal fluid was again examined one year after the attaining of blood seronegativity in 18 cases. All gave normal findings. The spinal fluid also of the 23 patients who had received the second course of treatment was reexamined. All were normal except 1, a young Negro woman treated for serologic relapse whose spinal fluid findings indicated a definite paretic curve six months after the first treatment.

Twenty-seven patients were treated in the seronegative chancre stage. Eight of these failed to return for observation. Of the remainder all but 1 remained seronegative, the longest observation being twenty six months. In the 1 case which was lost from observation for five months the history strongly suggested a new infection. Incidentally, of the 151 cases dropped from the study because of insufficient observation 19 had been treated for seronegative primary syphilis and 23 others had already attained seronegativity.

The best results were obtained in patients who reported for treatment early in the course of the disease, for serologic relapses occurred in only 2 of the 135 patients who had been treated for chancre. In the successful cases seronegativity usually occurred in the tenth week after treatment. In 1 case, however, the blood test did not give a negative reaction until twenty-two months after treatment. Among the patients who suffered relapse were a husband and wife who were treated for early syphilis within three weeks of each other. Other patients had been treated successfully at the same time and with the same lot of drug, yet both husband and wife exhibited lesions of cutaneous relapse.

There were no cases in which there was an appreciable alteration of the blood chemical findings, the blood picture or the icteric index. In 6 patients in whom five day treatment was interrupted because of the onset of complicating symptoms, daily injections of mapharsen by the syringe method were later well tolerated.

COMMENT

The method, to judge from the results of the experiment at the Cook County Hospital, has much to recommend it but there are certain disadvantages that cannot be disregarded. Of most importance is the danger of serious cerebral reactions, 1 case of a single convulsion and 2 of encephalopathy, in our group of 424 cases. Five of the patients who needed a second course of treatment refused it because of the nausea, headache and arm pain that they suffered the first time.

6a. Rattner, Herbert. The Treatment of Syphilis in Pregnancy by the Five Day Massive Dose Method, *Am J Obst & Gynec*, to be published.

6b. "Established criteria" require among other things that the new lesion be at a "site other than that of the primary lesion of the first infection."

7. Schoch, A. G., and Alexander, L. J. Reinfection or Relapse? A Newer Concept of Reinfection Encountered with Ten Day, Arsenic of Early Syphilis Controlled by Quantitative Serologic Tests. *Syph, Gonorr & Ven Dis* 27: 15 (Jan) 1943.

The treatment can be adapted to routine measures, for the dosage is the same regardless of the age or weight of the patient, and even the treatment of the reactions may be standardized, for they are relatively few in kind. The essential laboratory aids are simple to perform. Relatively little active nursing care is required, because the patients are permitted to leave the bed at the conclusion of the day's treatment. It is important, however, that the nurses be acquainted with the procedure, and the patients should be under their constant observation for early signs of reactions.

With this procedure there is no lapse of treatment. This is most important, for the dangers of inadequate treatment have often been stressed. Indeed, Padgett's⁸ careful study of long-term results in early syphilis led him to conclude that, "if continuous treatment cannot be given, no treatment is the desideratum." And it is known that the vast majority of infected persons, because of sheer ennui, do not persist through the lengthy course of conventional continuous therapy.⁹

There is much to be said also for the fact that the patient can have the treatment completed in one week. This feature alone has aroused an enormous interest. The patient, shocked as he usually is to learn that he has the disease, is psychologically conditioned to give complete cooperation before his remorse wears away, and the feckless one's cooperation can usually be sustained for a period of one week, though rarely longer.

However appealing the five day feature, of greater significance are the statistics which indicate that satisfactory results were obtained to date in approximately 95 per cent of the cases.

SUMMARY

1 The five day treatment method was studied in 481 cases of syphilis. Of this number 421 completed the full course of five day treatment, 310 of them with mapharsen alone and 111 with a combination of mapharsen and bismuth used concurrently.

2 There were no fatalities in the group, but there were 3 instances of serious cerebral reactions and a high incidence of unimportant minor reactions. Treatment was discontinued in 6 per cent of the cases because of the development of complicating symptoms. Three per cent of the candidates were rejected as unsuited for the treatment because of physical defects.

3 The study emphasized the value of reliably performed quantitative serologic tests as a therapeutic index and focused attention on the questions of reinfection and superinfection. In the group studied there were at least 15 instances of reinfection.

4 The period of observation is too short to permit final conclusions, but the results to date indicate that the use of mapharsen alone produced satisfactory results from one course of treatment in 86 per cent of the cases, one course of the arsenic-bismuth combination produced satisfactory results in approximately 95 per cent of the cases, and a second course of treatment administered usually six months after the first course apparently "cured" practically all of those who failed the first time.

THE USE OF PROSTIGMINE IN THE TREATMENT OF POLIOMYELITIS

HERMAN KABAT, M.D., PH.D.

AND

MILAND E. KNAPP, M.D.

MINNEAPOLIS

In recent years radical changes in the therapy of poliomyelitis have been advocated which have stimulated reinvestigation of the pathologic physiology of the disease. The Kenny concept has placed emphasis on neuromuscular changes which obviously cannot be explained by the well recognized lower motor neuron paralysis in this disease.¹ "Muscle spasm" and "incoordination" have been shown to be frequent and prominent symptoms of poliomyelitis.

"Muscle spasm" consists of at least two phenomena involving muscular hyperactivity in tonus and proprioceptive reflexes. The first phenomenon is a muscular rigidity or hypertonus which results in deformity (as in "foot retraction" or "foot drop") and limitation of passive motion (as in the rigidity of the back). The second type of change, which has been called "muscle spasm," is a limitation of passive motion which is at least in part the result of hyperirritable stretch reflexes in the muscles involved. As an example, in straight leg raising in subacute cases little or no resistance to passive motion is noted until a certain point is reached, when a decided resistance develops suddenly, associated with contraction and pain in the hamstring muscles. This appears to be a stretch reflex, the "trigger mechanism" of which is set at a lower level than normal. These changes in the muscles persist unchanged for months in many cases unless proper treatment is instituted early in the course of the disease.

Experimental studies on the mechanism of these phenomena have demonstrated that they have a neurogenic basis.² The muscular rigidity and hyperirritable stretch reflexes disappeared temporarily during spinal anesthesia in patients with poliomyelitis. On the other hand, intravenous pentothal anesthesia produced relatively little effect on the muscle spasm. These studies suggest that muscle spasm may be the result of changes produced in the gray matter of the spinal cord by the virus invasion. This view is corroborated by electromyographic recordings from hypertonic muscles in cases of poliomyelitis.³

An analysis of available sections of the spinal cord from 78 patients with poliomyelitis who died in the acute stage of the disease has revealed that inflammation about the internuncial neurons in the gray matter of the spinal cord occurred in almost every case and that injury to internuncial neurons appeared to be prominent in many cases.⁴ On the other hand little or no injury to anterior horn cells was observed in about 40 per cent

of the cases, while the other 60 per cent showed more or less pronounced destruction of the large motor neurons. In 1 case which had shown decided muscle spasm, the internuncial injury was severe while the anterior horn cells appeared to be unaffected. It has also been demonstrated in experiments on dogs that a localized lesion of the internuncial neurons in the spinal cord produced hypertonus of skeletal muscles similar to that observed in clinical poliomyelitis.⁵ The significance of the internuncial lesion becomes clear when one realizes that practically all impulses through reflex arcs as well as from higher centers, including the pyramidal tracts, must be relayed through the internuncial neurons to excite the large motor neurons in the anterior horn. In other words, an internuncial lesion should interfere with and disorganize synaptic transmission to the anterior horn cells. The muscular hypertonus and proprioceptive reflex hyperirritability could therefore be considered release phenomena resulting from removal or inhibition from anterior horn cells due to synaptic disorganization. "Incoordination" may also be explained, at least in part, by such synaptic disorganization resulting from injury to the internuncial neurons. The common occurrence of the internuncial lesion in poliomyelitis is further substantiated by the observation of Minckler⁶ that synaptic terminals on the surface of the anterior horn cells were degenerated as a result of injury to internuncial neurons in 8 cases of poliomyelitis studied by special staining methods.

THE EFFECTS OF PROSTIGMINE ON MUSCLE FUNCTION IN POLIOMYELITIS⁷

It is now generally believed that the fundamental effect of physostigmine and prostigmine is to depress the function of an enzyme called cholinesterase.⁸ This enzyme is responsible for the rapid splitting of acetylcholine, rendering this powerful substance physiologically inactive. By inhibiting cholinesterase, prostigmine allows acetylcholine to accumulate to a greater extent than normal at synapses, parasympathetic nerve endings and myoneural junctions and in the blood and in that way produces profound physiologic changes throughout the body.

In myasthenia gravis, prostigmine has a striking effect in relieving fatigue of skeletal muscles.⁹ In postencephalic Parkinson's disease, administration of prostigmine aggravates the muscular rigidity and tremor to a large extent.¹⁰ Fibrillation of denervated muscle is increased by the drug.¹⁰ Even in normal persons fascicular twitchings may be induced.⁸ All these actions of prostigmine have been attributed to the inhibition of cholinesterase at the myoneural junction of skeletal muscle.

The effects of prostigmine on muscle function in poliomyelitis have been studied in a series of 24 patients ranging in age from 2 to 46 years. The time from the onset of paralysis varied from three weeks to seventeen months. In 20 patients the effects of prostigmine were observed within an hour after sub-

cutaneous injection of 0.5 to 2.5 mg of prostigmine methylsulfate. The effects of oral prostigmine bromide have also been observed in these patients.

Early in the course of this investigation it was noticed that effects on the function of skeletal muscle were more severe with larger doses of the drug, producing unpleasant parasympathetic symptoms. Atropine sulfate given simultaneously with the prostigmine was found to eliminate these unpleasant parasympathetic effects while not producing any apparent inhibition of the important effects on muscle function. This made it possible to give larger doses of prostigmine together with atropine, producing more pronounced muscular effects and no unpleasant symptoms whatever. This combination of prostigmine and atropine has been used routinely in treatment. This will be discussed in more detail later.

The most significant effect of prostigmine on patients with poliomyelitis was the relaxation of muscle spasm. The decrease in hypertonus was accompanied by a decrease in muscle pain. There was also evidence that prostigmine decreased "incoordination" and in some instances increased active muscular contraction.

The muscle spasm was measured quantitatively by recording the range of passive motion allowed by various muscle groups before and after injection of prostigmine. Measurements were made by means of a goniometer and the range of passive motion was recorded in angles. The error in measurement is about ± 2.5 degrees. The increase in range of passive motion observed within an hour following injection of prostigmine in poliomyelitis patients is shown in table 1. These data show that the range of passive motion is increased significantly by this drug. The patients reported that their motions felt "looser." In some cases deformities decreased or disappeared. The hypertonic muscles also felt more elastic and less rigid to the examiner, and tendons and muscles stood out less noticeably and were softer and less painful on palpation.

A striking fact was that the extent of relaxation varied greatly in different muscle groups in the same patient. In some patients one pectoral muscle relaxed noticeably while the corresponding muscle on the opposite side showed no change in spasm. In others, the soleus relaxed while there was no change in the overlying gastrocnemius muscle in the same leg. Many other examples may be cited of localization and specificity in the action of prostigmine, although the drug is presumably distributed equally throughout the body.

Several types of deformities have decreased or disappeared following administration of prostigmine. In several instances "foot drop" due to hypertonus in the posterior calf muscles has been improved or eliminated. In 2 instances flexion deformity of the hand greatly decreased within an hour after subcutaneous injection of the drug. In 3 an elevated shoulder resulting from hypertonus of the upper trapezius has come down to a more normal position following prostigmine. These observations are the more significant since these deformities had been present for at least four months.

The increase in active motion observed following prostigmine seemed in some cases to be related to the decrease in muscle spasm in the antagonists. Six months after the onset of poliomyelitis in 1 instance active motion appeared for the first time in finger extensors one hour after subcutaneous injection of prostigmine and was accompanied by decided relaxation of the flexor muscles. Another patient at five and one-half months after the onset was able to raise his head from the table in the supine position for the first

time two days after initiation of prostigmine therapy. Other examples of increased active motion in arms, legs and trunk will be mentioned later in the discussion of treatment.

As mentioned in the introduction, "incoordination" of muscles, resulting presumably from disorganization of synaptic connections in the spinal cord is a frequent occurrence following poliomyelitis. In 1 case passive abduction of the arm resulted in jerky contractions of the biceps, wrist extensors and trapezius muscles. In some cases active or passive flexion of the thigh produced contractions in the adductors, sartorius or glutei. Hyperirritability of reflex arcs was so severe in 1 case that light tapping of the ribs produced a reflex twitch of both pectoral muscles, more severe on the ipsilateral side. In all types of "incoordination" in poliomyelitis patients, the abnormal muscle contractions in the superfluous muscles are frequently characterized by fascicular twitchings. "Incoordination" appeared to be definitely decreased in some patients by prostigmine.

Spontaneous fascicular twitchings following administration of prostigmine were observed in only 4 patients,

of action of the drug at the myoneural junction. These data suggest that the beneficial action of prostigmine observed in poliomyelitis may be the result of its inhibitory action on cholinesterase affecting synaptic function in the spinal cord. According to Sollmann,⁸ with increasing doses of physostigmine in animals the drug first affects the spinal cord and then the bulbar centers, and even with toxic doses consciousness is maintained until the end.

In order to demonstrate more conclusively the action of prostigmine on the spinal cord, the drug was injected intraspinally in 3 patients. The relaxation of muscular hypertonus was very much greater than had been observed following subcutaneous prostigmine. Furthermore, while the effect on muscle function was coincident with the parasympathetic actions following subcutaneous administration of the drug, the muscular relaxation appeared earlier than the parasympathetic effects following intraspinal prostigmine. The effects on muscle function preceded significant absorption of the drug into the general circulation. This rules out an effect on the myoneural junction of skeletal muscle.

all of whom were between 14 and 20 years of age. Fascicular twitchings from prostigmine were noted only in the face, upper part of the trunk and arms. In no instance were fascicular twitchings induced by prostigmine in a paralyzed muscle or a muscle in spasm even in cases in which motor denervation had produced well defined atrophy. The fascicular twitchings from prostigmine occurred one-half to one hour after administration of the drug, rarely persisted for more than an hour and were never followed by harmful after-effects.

The question arises as to the locus and mechanism of action of prostigmine in poliomyelitis. The fact that elimination of parasympathetic actions of the drug by atropine does not interfere with the effects on muscle function demonstrates conclusively that the muscular action is not secondary to general parasympathetic effects. The evidence also is clear that the changes in muscle function observed are not the result of the action of prostigmine on the myoneural junction in skeletal muscle. Accumulation of acetylcholine due to inhibition of cholinesterase at the myoneural junction could only increase hypertonus of skeletal muscle, while administration of prostigmine in poliomyelitis patients significantly decreased muscle spasm. The inhibition of hyperirritable stretch reflexes by prostigmine as well as the inhibition of "incoordination" cannot be the result

as the factor responsible for the muscular relaxation and points to the spinal cord as the locus of action of the drug. Kremer¹¹ has recently demonstrated depression of deep reflexes and spasticity from intrathecal injection of prostigmine in man. The effect is a local one on spinal centers.

These studies suggest, therefore, that prostigmine has important effects on the spinal cord in man which appear to be of value in the therapy of a disease of the spinal cord, poliomyelitis. They also suggest that the spinal cord may be more sensitive to prostigmine than the myoneural junction regardless of the route of administration. The depression of muscular hypertonus, stretch reflexes, "incoordination" and reflex hyperirritability after oral or subcutaneous administration of prostigmine seem to be the result of spinal action of the drug with no evident action on the myoneural junction. The increase in active motion observed following prostigmine may be due also to the action on the spinal cord rather than on the myoneural junction. Merlis and Lawson¹² have observed in dogs that following intravenous or intraspinal physostigmine

11 Kremer, Michael. Action of Intrathecally Injected Prostigmine and eserine on the Central Nervous System. *Ann. Quart. J. Exper. Physiol.* 31: 33-47 (July) 1936.

the flexion reflex was augmented while the knee jerk was depressed. They proved that these effects on reflexes resulted from the action of the drug on the spinal cord and that atropine failed to antagonize this spinal action.¹² Changes in reflexes were obtained with doses of physostigmine which did not affect the myoneural junction. The experimental evidence of these investigators also demonstrated that fascicular twitchings are due to the action of physostigmine on the spinal cord rather than on the myoneural junction. This view is supported by the observation previously mentioned that fascicular twitchings were never induced by prostigmine in paralyzed muscles in poliomyelitis patients, although denervated muscle is hypersensitive to acetylcholine.¹⁰

The mode of action of prostigmine on the spinal cord in man appears to be complex, the drug inhibiting some reflexes and augmenting others. In general, the proprioceptive functions such as muscle tonus and stretch reflexes appear to be inhibited by prostigmine in man, while active motion may be augmented. Merlis and Lawson¹¹ observed in dogs that physostigmine augmented reflexes from stimulation of the skin, such as the flexion reflex and the crossed extension reflex, while depressing the knee jerk (a modified stretch reflex, proprioceptive). They came to the conclusion that physostigmine acts on the synaptic connections to the anterior horn cells by influencing the function of the internuncial neurons. It will be recalled that evidence has been presented earlier that muscular hypertonus, hyperirritable stretch reflexes and "incoordination" in poliomyelitis may be related to a lesion of internuncial neurons. The beneficial action of prostigmine in poliomyelitis may therefore depend on localized action of the drug at exactly the site of abnormal function in the spinal cord. The fact that prostigmine relaxed spasm in some muscles and not in others in the same individual may perhaps be related to local differences in pathologic involvement of internuncial neurons and derangement of synaptic function in the spinal cord in poliomyelitis.

PROSTIGMINE AS AN ADJUNCT IN THE TREATMENT OF POLIOMYELITIS

Twenty patients suffering from poliomyelitis were given prostigmine subcutaneously, orally or by both routes as an adjunct in therapy. In almost all cases hot fomentations were continued throughout the period of prostigmine administration. Two of these patients were at the Gillette State Hospital for Crippled Children, St. Paul, 4 at the Elizabeth Kenny Institute, Minneapolis, 1 at St. Barnabas Hospital, Minneapolis, and 13 at the University of Minnesota Hospital, Minneapolis. Seventeen of the patients were in subacute stages of the disease, ranging from two to six months following the onset. There were 2 patients with acute poliomyelitis at three to four weeks after onset and 1 with chronic poliomyelitis at sixteen months after onset.¹³

The improvement following prostigmine was clearly demonstrable in many subacute cases despite the continuation of the other forms of therapy. The acute cases showed improvement immediately after initiation of prostigmine therapy that was apparently more rapid than the improvement usually noted in such cases with

hot fomentations alone. However, this is difficult to evaluate since the patients were progressing satisfactorily with the hot fomentations. A large series of acute cases will be necessary to establish the value of prostigmine. The 1 case studied sixteen months after the onset showed definite improvement, but more such cases must be investigated before one can say that prostigmine is of value in the chronic stage.

The usual procedure was to begin by careful examination of the patient including measurements of limitation of passive motion in angles. The progress of the patient under prostigmine therapy could be evaluated quite accurately by repeated measurements of range of passive motion. The treatment was begun by studying the effects of hypodermic injection of prostigmine. The prognosis could be estimated roughly by the improvement resulting from a single subcutaneous injection. The doses used were as follows: for adults, 1.5 to 2 mg of prostigmine methylsulfate together with $\frac{1}{400}$ gram (0.6 mg) of atropine sulfate, for children of 8 to 13 years, 1 mg of prostigmine with or without $\frac{1}{200}$ gram (0.3 mg) of atropine, for children of 2 to 6 years, 0.5 mg of prostigmine without atropine. With these doses the beneficial effects on muscle function were usually observed with no serious toxic symptoms. Subcutaneous injections were more effective than oral administration and were repeated when necessary in patients who did not respond rapidly.

Oral administration of prostigmine was begun in most cases after an initial injection of the drug, but in some cases oral doses alone were used. For adults the usual dose was gradually built up to prostigmine bromide 45 mg and atropine sulfate $\frac{1}{400}$ gram (given simultaneously) three times a day. The children of 12 to 14 years received prostigmine bromide 30 mg and atropine sulfate $\frac{1}{200}$ gram three times a day. Younger children were given prostigmine bromide 15 mg two to five times a day without atropine. These doses usually did not cause toxic or unpleasant symptoms but the balance of prostigmine and atropine had to be adjusted carefully to the individual patient to avoid such symptoms. Patients have taken these doses for two months without unpleasant or harmful effects, and almost all patients showed some improvement in muscle function from the drug.

The increase in range of passive motion resulting from prostigmine therapy is summarized in table 2. It will be noted that the improvement varied from patient to patient and in different muscles of the same patient. It seems likely that these differences in response to prostigmine may be related to local differences in the severity of disorder of the spinal cord.

REPORT OF CASES

CASE 1—F. B., a woman aged 30, was started on treatment one week after the onset of poliomyelitis. She had involvement of all four extremities at the onset and had difficulty in swallowing for three weeks. Three and one-half months after the onset she was unable to sit up and had pronounced weakness of both lower extremities, bilateral "foot retraction," limitation in range of passive straight leg raising and abduction of the lower extremities and stiffness of the back. There was considerable pain in the muscles on stretch or pressure. She was given two subcutaneous injections of prostigmine and atropine in one week and was then treated with oral prostigmine and atropine for two weeks, the medication being given in addition to hot fomentations. At the end of this time she was able to sit up easily, the foot retraction had disappeared, the back was much looser and passive abduction and straight leg raising were normal. She was able to stand and walk by

¹³ At our suggestion 4 patients were treated with prostigmine at the Wesley Memorial Hospital in Chicago. The results have been made available through the courtesy of Dr. Compere and are included in table 2. Dr. Bennett has treated 40 subacute cases of poliomyelitis with prostigmine at our suggestion at Warm Springs, Ga., with encouraging results.

herself without support. Despite discontinuance of the drugs and the hot packs, the patient retained the considerable improvement. There appeared to be definite acceleration of recovery from administration of prostigmine.

CASE 2—D G, a boy aged 9 years, was started on treatment two weeks after the onset of poliomyelitis. At five months after the onset, weakness of the muscles of the right arm and shoulder and sharp limitation of passive abduction and forward flexion were present. The patient was given oral prostigmine in addition to hot fomentations for five weeks. After two weeks he showed a great increase in range of passive abduction and forward flexion and some increase in strength in the right arm. At the end of the period of treatment with the drug, the limitation of passive motion had practically disappeared and there was a considerable increase in active motion in the deltoid, pectoral and coracobrachialis muscles in the right arm. The improvement was retained after the prostigmine therapy had been discontinued. The improvement appeared to be accelerated by prostigmine.

CASE 3—B C, a girl aged 17 years, was started on treatment ten days after the onset of poliomyelitis. Six months after the onset the patient had paralysis of the left arm with sharp limitation of passive abduction, forward flexion and external

rotation of both arms. There was rigidity of the back and the back of the neck, elevation of the right shoulder, great limitation of passive abduction, forward flexion and external rotation bilaterally at the shoulders. There was spasm of the triceps and biceps and flexion deformity of the hands. While continuing with hot fomentations, the patient was given an injection of prostigmine and atropine, and then the drugs were administered orally for a period of three weeks. At the end of this time there was considerable improvement in abduction, forward flexion and external rotation. The shoulder elevation had decreased, the biceps was relaxed and the flexion deformity of the hands had practically disappeared. There was no change in the triceps and little improvement in the rigidity of the back. There appeared to be acceleration of recovery due to administration of the drug.

CASE 5—R L, a boy aged 8 years, was treated beginning three days after the onset of poliomyelitis. Five and one-half months after the onset he had paralysis of both lower extremities and was unable to sit up, to turn over in bed or to raise his head while lying in the supine position. He had no contraction of the abdominal muscles in attempting to sit up, could not support himself with his arms either in the sitting position or in the prone position, and had decided weakness of the

* These patients were treated at our suggestion at the Wesley Memorial Hospital, Chicago, and the data have been made available through the courtesy of Dr. E. L. Comper.

rotation at the shoulder. There was considerable spasm in the left upper trapezius, in the wrist and finger flexors and in the triceps. The patient had a decided flexion deformity of the hand and the examiner was unable to straighten the fingers or extend the wrist. Considerable pain resulted from passive stretch of the hypertonic muscles. She was given one injection of prostigmine and atropine and then treated with oral doses of these drugs for two weeks, during which time the hot fomentations were continued. Within one hour after the injection the flexion deformity of the hand, which had been present for six months, completely disappeared. At the end of two weeks of therapy there was considerable improvement in passive abduction, forward flexion and external rotation at the shoulder. The triceps, trapezius, wrist and finger flexors were greatly relaxed. The most striking observation was the complete disappearance of the flexion deformity of the hand, which remains in normal alignment. In addition the patient showed weak active flexion and extension of the forefinger, which she had been unable to perform previously. Ten days later another injection of prostigmine and atropine produced further significant improvement within a few hours. Recovery appeared to be more rapid as a result of the administration of prostigmine.

CASE 4—M C, a woman aged 46, was started on treatment five months after the onset of poliomyelitis. Five and one-half months after the onset the patient had considerable involve-

ment of both arms. There was rigidity of the back and the back of the neck, elevation of the right shoulder, great limitation of passive abduction, forward flexion and external rotation bilaterally at the shoulders. There was spasm of the triceps and biceps and flexion deformity of the hands. While continuing with hot fomentations, the patient was given an injection of prostigmine and atropine, and then the drugs were administered orally for a period of three weeks. At the end of this time there was considerable improvement in abduction, forward flexion and external rotation. The shoulder elevation had decreased, the biceps was relaxed and the flexion deformity of the hands had practically disappeared. There was no change in the triceps and little improvement in the rigidity of the back. There appeared to be acceleration of recovery due to administration of the drug.

CASE 5—R L, a boy aged 8 years, was treated beginning three days after the onset of poliomyelitis. Five and one-half months after the onset he had paralysis of both lower extremities and was unable to sit up, to turn over in bed or to raise his head while lying in the supine position. He had no contraction of the abdominal muscles in attempting to sit up, could not support himself with his arms either in the sitting position or in the prone position, and had decided weakness of the

erectores spinae, rhomboid and teres major muscles. There was rigidity of the back with lumbar lordosis. There was considerable hypertonus in the hamstring, gastrocnemius, soleus and sartorius muscles. After an injection of prostigmine and atropine he was given oral prostigmine for three weeks. Along with drug administration he received hot fomentations for the first week only. For the following two weeks he was given the drug and manipulations, but the hot fomentations were discontinued because of boils. At the end of three weeks the patient was able to sit up by himself and turn easily in bed. He could easily raise himself with his arms in the prone position and could raise his head from the table in the supine position. There was considerable improvement in active motion in the erectores spinae, teres major and rhomboid muscles bilaterally. There was also great improvement in contraction of the abdominal muscles in attempting to sit up. The back was looser and the lumbar lordosis less severe. There was great relaxation of muscle spasm in all of the muscles involved except the sartorius, which showed little improvement. Very striking in this case was the first appearance of the ability voluntarily to raise his head from the table two days after the administration of prostigmine was started. The abdominal muscles contracted at the first time when he attempted to sit up a week after the medication was begun. Prostigmine appeared to accelerate recovery.

CASE 6—W T, a man aged 20, was started on treatment one month after the onset of poliomyelitis. Two and one-half months after the onset there was paralysis of both lower extremities and great weakness of the upper extremities. There was great rigidity of the back and limitation of passive motion resulting from spasm in the hamstrings, gastrocnemii, adductors, rectus femoris and quadriceps in the lower extremities and in the pectoralis, latissimus dorsi and trapezius muscles in the upper extremities. After one injection of prostigmine and atropine he was given these drugs by mouth for three weeks along with hot fomentations. At the end of this time the patient noted increased power in the upper extremities and improvement in turning over in bed and in sitting up. There was decreased spasm in the gastrocnemii, adductors and rectus femoris while the hamstrings relaxed only slightly and there was no improvement in the quadriceps. There was considerable improvement in passive abduction but no change in forward flexion at the shoulder and little improvement in the back. The drug appeared to speed up recovery in this case.

CASE 7—A M K, a girl aged 8 years, was started on treatment two weeks after the onset of poliomyelitis. At the time of admission she was walking with support. There was weakness in the lower extremities, although all muscles could contract except the toe extensors on the left. Three weeks after the onset there was spasm in the hamstrings, adductors, quadriceps, posterior calf muscles and the back. She was given several injections of prostigmine and oral prostigmine over a period of one month during which time hot fomentations were continued. There was rapid relaxation of the muscular hypertonus. The impression was obtained that the release of muscle spasm was more rapid than had been observed with hot fomentations alone. The day after adequate oral dosage of prostigmine was instituted the range of passive straight leg raising suddenly increased 15 degrees and 20 degrees on the two sides.

CASE 8—R P, a youth aged 18, was started on treatment one month after the onset of poliomyelitis. On examination four and one-half months after the onset the patient had decided limitation of passive motion in the hamstrings, quadriceps and adductors as well as rigidity of the back. He was given one injection of prostigmine and then oral prostigmine for one month, during which time the hot fomentations were continued. There was considerable improvement in the muscular hypertonus, although the progress in this case was not too encouraging.

CASE 9—V M B, a girl aged 5½ years, was started on treatment two weeks after the onset of poliomyelitis. At five weeks after the onset there was limitation of passive motion due to spasm in the hamstrings, adductors and posterior calf muscles and the back. The patient was given one injection of prostigmine and then the drug was administered orally for two weeks along with hot fomentations. The prostigmine may perhaps have increased the rate of relaxation of spasm in this acute case.

CASE 10—C W, a boy aged 9 years, was started on treatment one week after the onset of poliomyelitis. When examined six months after the onset he had paralysis and atrophy of the left upper extremity. There was decided limitation of passive abduction and forward flexion at the left shoulder. He was treated with oral prostigmine for six weeks along with hot fomentations, resulting in considerable improvement in the range of passive abduction and forward flexion, with little improvement in active motion. Relaxation of muscle spasm appeared to be accelerated by prostigmine.

CASE 11—A Z, a boy aged 11 years, was started on treatment two days after the onset of poliomyelitis. At five months after the onset there was little residual paralysis except in the abdominal muscles. However, limitation of passive motion was still present in the hamstrings, adductors and back. In attempting to touch the toes with the knees straight, the patient could only reach to within 6 inches of his toes. He was unable to sit up straight with the knees straight because of the limitation imposed by his hamstring muscles. After an injection of prostigmine the drug was given orally for one week, during

which time the hot fomentations were discontinued because of boils. After only one week of treatment with this drug, he could sit up straight with the knees straight and was able to touch his toes easily without bending his knees. There was considerable improvement in range of passive motion of straight leg raising and abduction, and there was a greater arch in flexion of the back. The drug therapy appeared to accelerate recovery.

CASE 12—M F, a woman aged 22, had a residual paralysis of the left leg and weakness of the right leg sixteen months after the onset. Because there was residual limitation of passive motion due to contraction of the hamstrings, posterior calf muscles and rectus femoris, the patient was given prostigmine. In attempting to touch the toes while standing with the knees straight, the fingers were 8 inches from the floor. One hour after an injection of prostigmine and atropine, the patient for the first time in sixteen months, was able to touch the floor with the knuckles of the proximal phalanges owing to relaxation of the hamstring muscles. Oral prostigmine and atropine were given for one week along with hot fomentations. At the end of this time there was improvement in the range of passive motion because of relaxation of the hamstrings, posterior calf muscles and rectus femoris.

This case demonstrates that prostigmine may be effective in the chronic stage of the disease in some patients. In one other patient at sixteen months after the onset one injection of prostigmine caused relaxation in the hamstrings of one leg, but none of the other contracted muscles relaxed at all. In another patient at one and one-half years after the onset there was considerable relaxation of the hamstring and the shoulder muscles within an hour after injection of prostigmine and atropine. This leads one to hope that at least some of the more chronic cases may respond to this treatment.

CASE 13—M G, a girl aged 13, was started on treatment two weeks after the onset of poliomyelitis. She had paralysis of the entire body, widespread severe spasm and severe pain and tenderness at the onset. Three months after the onset the patient had well defined weakness and paralysis of the muscles of all four limbs, severe rigidity of the back and spasm of the hamstrings, quadriceps, posterior calf muscles and adductors in the lower extremities and in the pectoral and latissimus dorsi muscles in the upper extremities. She was unable to sit up, roll over in bed or use her arms effectively. Beginning three months after the onset she was given oral prostigmine and atropine for five weeks along with hot fomentations. Then she was given oral prostigmine and atropine and a subcutaneous injection of these drugs every evening for another week and oral medication alone for an additional two week period. At the end of this time the patient could sit up and turn over with ease. She could use her arms much better although they were still weak. There was great relaxation of spasm in the hamstrings, quadriceps, posterior calf muscles and adductors. The rigidity of the back was much improved, as was the spasm in the shoulder muscles. The drug appeared to accelerate recovery.

CASE 14—F K, a boy aged 14, was started on treatment one day after onset of paralysis. On admission he had complete paralysis of both lower extremities. Six months after the onset he had severe atrophy and paralysis in the muscles of the lower extremities. He had moderate spasm in the hamstring, gastrocnemius and adductor muscles and rigidity of the back. He was unable to sit up straight with the knees straight. Beginning six months after the onset he was given oral prostigmine and atropine for three weeks along with hot fomentations with some improvement. The drugs were discontinued for ten days and then he was given daily injections of prostigmine and atropine for one week. At the end of this time there was decreased spasm in the hamstring, gastrocnemius and adductor muscles and slight improvement of the back. He was able to sit up straight with the right knee straight and with the left knee slightly flexed. There was no improvement in active motion. The drug therapy apparently speeded up recovery.

CASE 15—L J, a man aged 44, was admitted to the hospital one day after onset of paralysis. On the way to the hospital the ambulance collided with a street car and he suffered a head injury. Proper treatment could not be carried out effectively for one month after the onset because of delirium. Five and one half months after the onset the patient had paralysis and atrophy of the muscles in the lower extremities and decided weakness and some atrophy in the right arm. There was severe spasm in the back, the hamstring quadriceps and adductor muscles in the lower extremities and in the shoulder muscles particularly on the right side. The right shoulder was elevated by upper trapezius hypertonus and there was severe spasm in the pectoral and latissimus dorsi muscles. Six months after the onset after two injections of prostigmine and atropine in the course of one week oral administration of the drugs was begun and continued for three weeks. At the end of this period the patient was given an intraspinal injection of prostigmine. The medication was given along with hot fomentations. At the end of the period of drug therapy there was considerable relaxation of the spasm in the hamstrings quadriceps adductors in the lower extremities and in the right shoulder muscles as well as a moderate decrease in rigidity in the upper part of the back. The patient was able to hold his knees drawn up in bed while formerly they had to be supported with pillows. There was increased active motion and strength in the right arm. There appeared to be some acceleration of recovery as a result of prostigmine administration.

CASE 16—E F, a boy aged 12 was started on treatment one month after the onset of poliomyelitis. Three and one-half months after the onset he was unable to sit up and had decided weakness of the lower extremities. He had severe spasm of the hamstring gastrocnemius adductor and back muscles and slight residual spasm in the shoulder muscles. There was still considerable pain on stretching the muscles. Three and one-half months after the onset treatment with oral prostigmine and atropine was begun along with hot fomentations. After ten days the treatment was discontinued temporarily because the patient had an upper respiratory infection. After two weeks oral prostigmine was resumed with occasional injections of prostigmine and atropine. At the end of the period of drug therapy the patient was able to sit up and had improved active motion in both upper and lower extremities. There was considerable improvement in the rigidity of the back and in the spasm of the hamstring, gastrocnemius and adductor muscles in the lower extremities while the hypertonus had disappeared from the upper extremities. The recovery appeared to be accelerated by drug therapy.

CASE 17—O M, a man aged 30 was started on treatment one month after the onset of paralysis. Four and one-half months after the onset the patient had moderate paresis of the lower extremities especially the right. There was still moderate rigidity of the back and spasm of the hamstring and adductor muscles, so that the patient was unable to sit up straight with the knees straight. He was given oral prostigmine and atropine along with hot fomentations for two weeks. At the end of this time he could sit up straight with the knees straight. There was much improvement in the rigidity of the back and in the spasm of the hamstring and adductor muscles. There was no significant change in active motion. The patient appeared to benefit from prostigmine therapy.

CASE 18—G H, a woman aged 25 was started on treatment six weeks after the onset of paralysis. She had severe involvement of all four extremities at the onset more pronounced in the left arm and leg. Five months after the onset she had weakness of the upper extremities and paralysis of the lower extremities. She was unable to sit up support her body on her elbow in bed or roll over. There was very pronounced rigidity of the back and severe spasm in the hamstring gastrocnemius soleus quadriceps and adductor muscles in the lower extremities and in the shoulder muscles particularly on the left. Five months after the onset prostigmine and atropine therapy was begun and continued along with hot fomentations for eight weeks. At the end of this time there was considerable improvement in active motion in the upper extremities with almost complete disappearance of the hypertonus in the shoulder.

One week after drug therapy was begun, the patient noticed that she could lift her trunk on her elbow and could support her weight, which she had tried to do many times before and had never succeeded in accomplishing. There was great improvement in the spasm in the hamstring, quadriceps gastrocnemius soleus and adductor muscles and some improvement in rigidity of the back. The drug therapy appeared to accelerate recovery.

CASE 19—A E, a man aged 36, had a very severe involvement of the entire body and was only able to move his head fingers and toes weakly. While he had been admitted to another hospital one day after the onset his treatment was inadequate. When first seen six months after the onset he had paralysis of all four extremities and was able to move only his fingers and toes. He had an extreme degree of rigidity in the back, severe spasm in the hamstring and quadriceps muscles in the lower extremities and pectoral latissimus dorsi triceps and pronator muscles in the upper extremities. He was given oral prostigmine and atropine as well as frequent injections of these drugs for three weeks, along with hot fomentations. He showed practically no improvement either in active motion or in relaxation of muscle spasm. There was temporary relaxation after injection of prostigmine and atropine but the improvement was not retained.

CASE 20—T G, a boy aged 2 years, began treatment five weeks after the onset of poliomyelitis. Four and one-half months after the onset the patient had paralysis of the muscles of the left leg and weakness of the left soleus and quadriceps muscles. There was also a foot drop on the left with pes cavus due to hypertonus in the plantaris and soleus muscles. Oral prostigmine was given along with hot fomentations for two weeks and then repeated injections of prostigmine were given for another ten days. There was no improvement in active motion and relatively slight relaxation of the hypertonus.

It is difficult to evaluate the improvement resulting from therapy in poliomyelitis. The disease is variable in the distribution and severity of involvement as well as in its course. Therefore it is often a problem to predict accurately the rapidity of recovery that would have ensued had treatment not been given. An additional variable was introduced in this investigation by the fact that hot fomentations were continued during the period of prostigmine therapy. In several cases rapid progress was seen with prostigmine although the hot fomentations were discontinued during this period. The rapidity of improvement with prostigmine therapy in some cases suggests definite therapeutic benefit from the drug. In other cases one could not be certain that the improvement was due to the drug, 2 patients with severe involvement showed little recovery.

SUMMARY AND CONCLUSIONS

1 Prostigmine decreases skeletal muscle hypertonus and proprioceptive reflex hyperirritability ("muscle spasm") in patients with poliomyelitis. It also reduces 'incoordination'. These effects may be evident one hour after subcutaneous administration of the drug. These actions of prostigmine apparently depend on alteration of function of synapses in the spinal cord and are not antagonized by atropine.

2 Prostigmine has been given a preliminary trial as an adjunct in the treatment of poliomyelitis. The approach to therapy has been based on the Kenny concept of the disease. In a series of 20 patients most of whom were in the subacute stage of the disease the results have been encouraging. The drug significantly increased the range of passive motion, decreased or eliminated deformities in some instances by relaxation of hypertonus and in some cases improved active motion. In a number of instances muscle spasm has shown more rapid improvement when prostigmine was added to the Kenny routine. In a majority of cases the drug appeared to accelerate recovery.

THE RELIABILITY OF CHEMICAL TESTS FOR ALCOHOLIC INTOXICATION

THE IMPORTANCE OF THE SELECTION OF PROPER MATERIAL FOR ANALYSIS

LESTER D ELLERBROOK, PHD
Toxicologist, City of Kingston Laboratories

AND

CHESTER B VANGAASBEEK, MD
Attending Surgeon Kingston Hospital
KINGSTON, N. Y.

The successful prosecution of violators of the drunken driver laws is dependent on an accurate medical diagnosis and the proper presentation of the evidence in court. Many physicians have found by painful experience that the usual symptoms of alcoholic intoxication do not necessarily establish this diagnosis. It is essential not only to examine the suspect thoroughly but also to demonstrate the presence of enough alcohol in the body tissues to produce these symptoms, for it may be necessary to prove beyond a reasonable doubt that the impairment of the ability of the driver to operate a motor vehicle was the result of the effects of alcohol and was not due to other drugs or to such conditions as fatigue, injury or disease.

The reliability of chemical tests for intoxication has been the subject of much dispute, but the results of our studies indicate that there is a definite correlation between the degree of intoxication determined clinically and the alcohol content of properly selected body fluids. The severity of the symptoms of alcoholic intoxication in human beings under the usually encountered conditions has proved to be practically proportional to the venous blood alcohol concentration within the limits of normal biologic variation. A study of the literature on this subject, the results obtained in a series of experiments and our experience with drunken drivers have convinced us that the chemical analysis of venous blood for alcohol is the most valuable aid in the diagnosis of intoxication because it can furnish definite objective evidence of intoxication and, of equal importance, evidence of sobriety.

Since June 1938 the Kingston Police Department has routinely used chemical tests of blood and urine in all of its drinking driver cases. The suspects were given a thorough clinical examination by the police surgeon (C B VanG) and specimens of both urine and venous blood were obtained whenever possible. The specimens were examined (L D E) by the methods of Heise,¹ and in cases which might come to trial in the courts the results were checked by another reliable method.² In our study of 101 cases we were voluntarily given permission to obtain 79 specimens of urine and 98 specimens of blood, while in 76 of these cases specimens of both blood and urine were secured.

The results of this procedure have been very satisfactory from the medical standpoint because in every case in which the examining physician made a diagnosis of intoxication he was confident that the person was not

being unjustly accused. The physician believed several persons to be sober, and these opinions were confirmed by the finding of little or no alcohol in the specimens examined. The blood alcohol level has indicated the degree of intoxication in all but a few cases, and furthermore the physician has learned how to predict the blood alcohol concentration with a high degree of accuracy. The medicolegal value of this routine is demonstrated by the fact that 70 per cent of those accused of driving while intoxicated entered pleas of guilty. Several persons who stoutly maintained their innocence pleaded guilty on being told that the concentration of alcohol in the blood indicated that they were intoxicated. The number of convictions in court, however, has been disappointing. Only 1 of the 8 drivers tried in the city court has been convicted, although the 2 drivers tried in the county court were found guilty.

CORRELATION OF ALCOHOL CONCENTRATION AND SYMPTOMS

The use of chemical tests for intoxication depends on a proportionality between the severity of the symptoms and the concentration of alcohol in the material tested. The existence of this proportionality has been the subject of much controversy and discussion.

The American Medical Association's Committee to Study Problems of Motor Vehicle Accidents³ has reported that "the concentration of alcohol in the blood is one of the best criteria of intoxication because blood alcohol concentrations closely parallel detrimental effects noted in carefully conducted experimental tests. Although this relationship is not mathematically exact because of slight variations resulting from inherent differences in human beings, it is sufficiently accurate for practical purposes." The committee concluded that a blood alcohol concentration of greater than 0.15 per cent is conclusive evidence of intoxication and that levels of from 0.05 per cent to 0.15 per cent are often associated with mild intoxication. It was recommended that drivers having blood alcohol concentrations of less than 0.05 per cent should not be prosecuted. The National Safety Council's Committee on Tests for Intoxication⁴ has come to similar conclusions, and practically identical interpretations have been incorporated into the laws of several states.

Mozes and Katonak⁵ go so far as to state that, "as far, at least, as the operation of a motor vehicle is concerned, the alcohol concentration of various body fluids and expired air furnishes a far more reliable index of the degree of alcohol influence than the most careful and detailed clinical study." There are investigators, however, who believe that there is only a very general correlation with distinct exceptions in individual cases,⁶ while still others are convinced that there is little, if any, correlation between alcoholic concentrations of body fluids and the symptoms.⁷

This wide divergence of opinion might be explained by the observations of Mellanby and others⁸ that the symptoms are more severe at a particular blood alcohol level when the concentration is increasing than when it is decreasing. To our knowledge this effect has not been demonstrated by work in which there has been a critical selection of specimens for analysis and when human subjects were drinking alcoholic beverages in repeated small amounts in the usual manner. It is more probable that this disagreement is largely the result of the following:

1 Many of the investigations reported have consisted of experiments on laboratory animals only. Obviously conclusions drawn from such experiments are not necessarily applicable to man.

2 Some of the results reported after experiments on human beings may not be applicable to the usual intoxicated driver because these results were obtained under severe and unusual conditions by having the fasting subjects ingest large amounts of alcohol in a short period of time. These conditions are not encountered in the customary use of alcohol.

3 The criteria used for judging intoxication have undoubtedly varied from one investigator to another.

4 The alcoholic content of the various body fluids and tissues and of the breath are not comparable under all conditions. The disregard of this fact is undoubtedly responsible for many of the discrepancies found in the literature.

CHOICE OF MATERIAL FOR ANALYSIS

Since alcoholic intoxication is usually manifested by a wide variety of mental disturbances and neuromuscular incoordinations, it is reasonable to assume that if there is any proportionality between the degree of intoxication and the alcohol content of any tissue such a relationship would involve the central nervous system. The existence of such a relationship in both dogs and human beings has been demonstrated by Gettler,⁹ who found that when the alcohol content of the brain reached a level of approximately 0.25 per cent there was a resulting gross lack of neuromuscular coordination which was manifested by a staggering gait. Slight symptoms appeared at a concentration of approximately 0.10 per cent and became more noticeable as the concentration of alcohol increased.

Obviously the alcohol content of the brain of a living individual cannot be determined directly, and for this reason various other body fluids and excretions have been analyzed on the assumption that their alcohol contents reflect that of the brain. Most American investigators have hesitated to obtain specimens of blood in medicolegal cases and have therefore calculated the blood alcohol concentration from the results of the analysis of urine or of expired air. The committee of the American Medical Association³ states that the relationship between the concentrations of alcohol in the blood, urine, saliva and breath are sufficiently definite so that chemical tests of any one of these materials can furnish a "reliable measure of the degree of alcoholic influence." The existence of such relationships under all conditions however is questionable. In the light of the very definite critical levels of blood alcohol concentration now widely used for the interpretation of the results of the chemical analysis for alcohol, the relative errors involved in the use of urine, breath and blood are of great importance.

Urine.—A number of investigators have determined the ratio of the alcohol concentration of the urine to that of the blood by experimental methods. Some of the early workers¹⁰ reported that the alcohol concentrations of urine and blood are practically identical. Miles¹¹ using very low blood alcohol concentrations concluded that the urine-venous blood alcohol ratio is near unity in the first half hour after the ingestion of alcohol but that then "for an hour or more" it is 1.35 to 1.50. He obtained individual ratios of from less than 1.1 to more than 2.1. Southgate and Carter¹² using blood alcohol concentrations of from approximately 0.10 to 0.20 Gm per hundred cubic centimeters, determined this ratio at one, two and one-half and six and one-half hours after the ingestion of alcohol. They stated that "when alcohol is drunk on an empty stomach the ratio of these concentrations of alcohol after one hour is a fairly constant figure of the order of 1.35. In a series of experiments in which the subjects had also ingested food the average value for this ratio after two and one-half and six and one-half hours was 1.40.1 with a range of 1.25 to 1.67. They concluded that the concentration of alcohol in the urine is proportional to that of the blood "under all conditions so far examined." This average value of approximately 1.35.1 has been widely quoted as being that of the usual urine-blood ratio¹³ and the National Safety Council advises the use of this ratio in the interpretation of the urine alcohol concentration.

Similar although slightly lower average ratios have been obtained by the examination of intoxicated drivers and alcoholic hospital patients when the specimens were obtained at varying unknown intervals after the social use of alcohol. Bavis¹⁴ reported an average ratio of 1.17.1. We have calculated from his data that the range of values was 0.81 to 1.65. Jetter¹⁵ obtained an average urine-venous blood ratio of 1.23.1 with a range of 1.0 to 2.3. Mozes and Katonak¹⁶ reported an average urine-blood ratio of 1.16.1. Their data indicate a range of values of 0.63 to 1.77. Stratton¹⁶ has reported the following very definite relationship between the urine alcohol content and that of the brain. The percentage of alcohol in the brain equals 0.84 times the percentage in the urine minus 0.04 per cent of alcohol.

We have obtained a similar average urine-venous blood alcohol ratio of 1.26.1 in a series of 76 drinking drivers. The range of values was 0.69 to 1.71. Chart I demonstrates the degree of correlation between the blood and urine alcohol concentrations that may be expected in drinking driver cases.

Although all the reported average ratios are of the same order of magnitude as the average value obtained by Southgate and Carter under strictly controlled conditions it is evident that this ratio may vary widely from the average in the individual case. For this reason any blood alcohol level calculated from the

16 Stratton, Frank. Calculating the Blood Alcohol Content from the Urine. Am. J. M. J. 5: 1-2 (Jan.) 1927.

concentration of alcohol in the urine may vary greatly from the true value. This fact was pointed out by Haggard and his associates,¹⁷ who stated that, although the concentration of alcohol in the metenal urine is proportional to that simultaneously in the blood, the concentration in the bladder urine may not show this correspondence because the metenal urine is immediately mixed with urine which has previously accumulated in the bladder. They obtained an average urine-capillary blood alcohol ratio of approximately 1:3:1 when urine was voided at thirty minute intervals, but the ratio tended to be somewhat lower during the first hour after the ingestion of alcohol while rapid absorption was taking place. If the specimens of urine were collected at intervals of greater than thirty minutes, the ratios varied considerably. They suggested that after the first hour fairly reliable estimates of the alcohol concentration of the blood may be made from that of the urine by having the subject empty his bladder, discarding this specimen and examining another specimen voided thirty minutes later. Unfortunately, it is frequently impossible to secure even a single specimen of urine from a drunken driver. No doubt the difference in the times of collection of specimens of bladder urine is an important reason for the wide range of ratios obtained in medicolegal cases.

Chart 1—Venous blood and urine alcohol concentrations in 76 cases

The possibility of a great variation between the alcohol content of blood and that of urine in the individual case becomes of great importance in drinking driver cases in view of the very definite critical levels of blood alcohol concentration that have been recommended. A small urine to blood conversion error at a blood alcohol concentration near one of the critical levels may profoundly influence the medical and the legal interpretation of the results. The difficulties that may thus arise are demonstrated by some of our experiments.

In 1 case the actual venous blood alcohol concentration was 0.18 Gm per hundred cubic centimeters and the concentration in the urine was 0.14 Gm per hundred cubic centimeters thirty minutes after the ingestion of six highballs over a period of two hours. The bladder had last been emptied just prior to the ingestion of the last drink. The blood alcohol concentration calculated from that of the urine by the use of a ratio of 1:3:1 was 0.11 Gm per hundred cubic centimeters. This calculated value is below the 0.15 per cent critical level, although the actual blood concentration was well above this level.

In another experiment the specimens were obtained ten minutes after the ingestion of four highballs over a

period of three hours. The urine had accumulated in the bladder for a period of one and one-half hours. The venous blood alcohol concentration was 0.11 Gm per hundred cubic centimeters, the urine concentration was 0.07 Gm per hundred cubic centimeters and the calculated blood value would be approximately 0.05 Gm per hundred cubic centimeters. In this case the calculated value lies just at the lower critical level, although the actual concentration exceeded this by 120 per cent and the subject was slightly intoxicated.

Apparently the extent of the possible errors involved in the calculation of the blood alcohol content from that of the urine has not been realized by many investigators. Since such calculated blood alcohol levels may be grossly inaccurate, any precise conclusions drawn from these figures are unjustified. A widely quoted statement of the Committee on Tests for Intoxication⁴ is an example of such a conclusion. The committee has calculated from the data of Holcomb¹⁸ that the average driver with a blood alcohol concentration of 0.15 per cent or more is fifty-five times more liable to have a personal injury accident than is a driver with no alcohol in his blood. At 0.11 to 0.15 per cent the chances are calculated to be 15 to 1, at 0.07 to 0.11 per cent they are 5 to 1, and at concentrations of less than 0.07 per cent they are said to be 3 to 1. That there is such a general increase of liability to be involved in accidents with increasing blood alcohol concentrations cannot be denied, but, since the blood alcohol concentrations were calculated from those of urine or of breath, the actual mathematical relationship reported is questionable.

Breath—Bogen¹⁹ was one of the first investigators to study the correlation between the concentration of alcohol in the breath and that in the blood and urine. He reported that the alcohol content of 2 liters of expired air was slightly greater than that of 1 cc of urine. Later Harger and his co-workers¹⁹ developed a method for the analysis of expired air which was based on the assumption that the quantity of alcohol in 2,000 cc of alveolar air is equivalent to that in 1 cc of blood. In this method both the amount of alcohol and that of carbon dioxide in a specimen of expired air are determined, and the amount of alveolar air contained in the expired air is calculated on the assumption that 2,000 cc of alveolar air contains 190 mg of carbon dioxide. Tests made on a series of 121 persons showed a good average correlation between the amount of alcohol in 1 cc of blood and the amount accompanying 190 mg of carbon dioxide in the breath, but there were variations of as much as 50 per cent in individual cases. This method has been widely used in the chemical diagnosis of intoxication.²⁰

Jetter and Forrester²¹ have developed a method based on similar physiologic principles with the exception that the amount of alcohol accompanying 200 mg of carbon dioxide is determined. They emphasize a number of possible errors both technical and those relating to the test subject. The authors point out that there may be a normal variation of 15 per cent from the average carbon dioxide content of alveolar air and that this variation may be still greater under abnormal conditions such as acidosis and the alkalosis following emesis. The

average degree of correlation between the results of blood and breath analyses by their method was good but their data show individual errors of as much as 100 per cent especially at low blood alcohol levels.

Recently Haggard and his associates²² have stated that the coefficient of distribution of alcohol between air and blood is not 1:2,000 but 1:1,300. They also state that the alcohol concentration in lung air cannot be correctly calculated from that in mixed expired air on the basis of their respective carbon dioxide contents.

In addition to the technical errors inherent in the methods now in general use there is the disturbing possibility, especially at low levels during the rapid absorption of alcohol, that the alcohol concentration of the blood circulating through the lungs may not represent that of the brain. It is apparent therefore, that much of the work reported in the literature in which the blood alcohol concentration has been calculated by analysis of the breath will not be known for its accuracy.

Blood—Because of the possible and probable errors involved in the indirect estimation of the blood alcohol concentration from that of urine or of expired air it is probable that the analysis of the blood itself will demonstrate a closer correlation between the blood alcohol concentration and the severity of the symptoms. Especially will this be true if the alcohol content of the specimen examined is proportional to that of the brain.

Various values have been given for this blood-brain alcohol ratio. Bogen²³ stated that the alcohol concentration in the brain reaches a slightly higher level than that in the blood. Holcomb¹⁸ stated that after absorption the blood-brain ratio is 1.2:1. Stratton¹⁶ reported the blood-brain alcohol relationship in a series of 200 human cases to be as follows: "Percent alcohol Brain equals minus 0.02 per cent plus 1.01 (per cent alcohol Blood)." Newman and Lehman²⁴ have found that the cardiac blood-brain alcohol ratio is approximately 1.37:1 in rats.

This variety of opinion as to the relative alcohol concentrations of blood and brain might be explained by the statement of Haggard and Greenberg²⁵ that during the absorption and distribution of alcohol throughout the body the concentration in the blood leaving the brain through the jugular vein is the most reliable easily available indicator of the brain alcohol concentration. They have demonstrated the possibility of considerable variation between the alcohol contents of blood drawn from different sources by an experiment performed on a dog. Alcohol was administered to the fasting animal in a dosage of 3 Gm per kilogram of body weight, and the alcohol concentrations in specimens of blood obtained from various sources were determined at intervals. Under these extreme conditions the concentration in the arterial blood rose abruptly and that in the jugular blood increased more slowly while that in the blood from the femoral vein lagged so far behind that it was less than half that of the arterial blood at thirty minutes after ingestion. The

concentration in the blood from a skin capillary was slightly higher than that of the jugular blood during rapid absorption. With a decrease in the rate of absorption the four concentrations approached one another in value until they were practically identical after ninety minutes. The authors conclude that the alcohol content of blood drawn from a limb vein during the period of active absorption has "no general significance."

This extreme statement is not supported by the findings of Harger and his associates²⁶. These investigators determined the speed with which various parts of the body reach equilibrium in the storage of alcohol by administering varying amounts of alcohol to 53 dogs either intravenously or by mouth. Groups of from 3 to 7 animals were killed at intervals and the alcohol concentrations in various parts of the body were determined. The majority of these dogs were subjected to

the same severe conditions which had been employed by Haggard. A summary of some of the results as calculated from their data is presented in table 1.

A study of the average values for each group of animals indicates that during the early rapid absorption of alcohol under these extreme conditions (3 Gm of alcohol per kilogram) the brain alcohol concentration increased more rapidly than that of the blood in the saphenous vein. This would be expected from the findings of Haggard and Greenberg.²⁵ After only fifteen minutes however the venous blood concentration had overtaken that of the brain and at thirty minutes, although absorption was but 57.5 per cent complete and both concentrations were still increasing the blood and brain were already in alcoholic equilibrium. The actual alcohol concentrations obtained were somewhat greater than those reported by Haggard but the slope of the curve obtained by plotting time against the alcohol concentration of the blood taken from the superficial

saphenous vein is similar to that obtained by Haggard with blood returning from the brain through the jugular vein, it does not resemble the curve of the blood from the deep femoral vein. The average blood-brain alcohol ratio at equilibrium was approximately 1.28:1, but it should be noted that there was considerable variation between individual animals in the same group. Even when the effects of varying rates of absorption were eliminated by the intravenous administration of alcohol, the individual ratios of this small group of animals varied by as much as 11 per cent from the mean. A disregard of this normal biologic variation has undoubtedly been a source of considerable confusion.

Gettler and Freireich⁹ have performed a series of somewhat similar experiments on 8 dogs, 4 of which had been accustomed to the daily ingestion of alcohol over a period of six to twenty-four months. The fasting dogs were given amounts of alcohol varying from 1.9 to 5.6 gm per kilogram of body weight and they were then killed at intervals of from forty-five to one hundred and forty-seven minutes. Some of their results have

series of 20 coroner's cases, and the results obtained have been presented in table 2. In most instances the autopsies were performed within two to three hours of the time of death. Most of these persons had been involved in automobile accidents, and 9 of them were killed instantly while others died after varying periods of time. Undoubtedly this series of cases represents a fair cross section of the various stages of absorption and of the alcohol concentrations usually encountered in medicolegal work. The 3 persons who lived more than four hours after taking their last drink were undoubtedly in a state of alcoholic equilibrium. The average ratio (grams of alcohol per hundred cubic centimeters of cardiac blood to grams of alcohol per hundred grams of brain) in these 3 cases was 1:1. In each of 6 cases, including these 3, the alcohol concentration of the stomach contents was less than 0.2 per cent higher than that of the blood. The average ratio in these 6 cases in which absorption had practically ceased was 1.01:1, while the average ratio in the other 14 cases in which the stomach contents contained higher percentages of unabsorbed alcohol was 1.15:1. Apparently the blood-brain equilibrium ratio in human beings is lower than that in dogs and that in rats.

The cardiac blood-brain ratios in the entire series of cases representing various stages of absorption varied from 0.88 to 1.52:1. The one extremely high ratio was obtained in a person who died while rapid absorption was still taking place after he had ingested 5 pints of liquor on a wager. With the exception of this 1 case, which is not typical of persons driving automobiles, the maximum difference between the alcohol concentration of cardiac blood and that of the brain in any 1 case was 0.05 per cent of alcohol. The average blood-brain ratio was 1.09:1 with a range of values of 0.88 to 1.31:1.

The data in tables 1 and 2 indicate that even during rather rapid absorption of alcohol in dogs there is a practically constant relationship between the concentration of alcohol in the brain and that in the blood of a superficial vein. In human beings, in the stages of absorption sometimes encountered in medicolegal work, the alcohol concentration of arterial blood may be significantly higher than that of the brain. Under the usual conditions of relatively slow absorption, however, the concentration in the brain tends to lag only slightly behind that of arterial blood. The concentration of alcohol in the blood of a superficial vein may also lag slightly behind that of arterial blood, but under the usual conditions of social drinking the diffusion of alcohol from the capillary blood to the tissues probably keeps pace with the relatively long gradual process of absorption. The results obtained with dogs under extreme conditions would indicate that in drinking drivers the concentration in the venous blood obtained from the usual source, although slightly less than that of arterial blood, is probably essentially that of the brain. It is apparent, therefore, that the concentration of alcohol in venous blood is the best indicator of brain alcohol concentration in common use. Under the usual conditions in which the specimen is obtained some time after the ingestion of the last drink, both capillary and venous bloods will probably give practically identical results. At concentrations near the legal critical levels, however, the use of capillary blood may possibly result in an unjustified accusation, whereas any slight error involved in the use of venous blood would tend to favor the driver.

also been presented in table 1. The source of the blood analyzed is not stated, but at forty-five minutes from the time of the ingestion of a single large portion of alcohol the ratio of the alcohol content of the blood, whatever its source, to that of the brain was essentially that obtained by Harger and his associates with blood from the saphenous vein. The average ratio for all dosages and times was also similar to that obtained by Harger. Apparently the blood-brain ratio was not affected by the drinking habits of the dogs. Gettler and Freireich⁹ have also reported the results of the analyses of the blood and brain in a series of 15 human cases coming to autopsy. The source of the blood is not stated. They found a considerable variation in the blood-brain ratio, especially at very low alcohol concentrations, in which the effects of varying rates of absorption and the existence of minor technical errors would tend to accentuate any differences between such ratios. If the three sets of data which involve alcohol concentrations of 0.02 per cent or less are omitted there is less variation, and the average ratio is found to be 1.05:1, with a range of 0.63 to 1.47. We have determined the alcohol concentration of the brain and that of the blood in the right ventricle in a

In the light of this information we believe that the critical levels of blood alcohol concentration now so widely employed should be the basis of precise interpretations only when venous blood has been analyzed. At concentrations definitely above the critical levels, however the other frequently used body materials—capillary blood, urine or breath—will undoubtedly furnish valuable confirmatory evidence of intoxication.

Chart 2.—The results obtained by Heise and Halporn in 26 cases injured ** urine obtained two and one-half hours later

VENOUS BLOOD ALCOHOL CONCENTRATION AND THE DEGREE OF INTOXICATION

An individual becomes intoxicated by a gradual process and not through a series of definite stages, and for this reason it is frequently difficult to determine the precise extent of this gradual deterioration of physical and mental function. This is especially true because of the fact that the signs and symptoms of intoxication may be altered by such other factors as fatigue and the emotional stability of the individual. Another factor, well known to many drinkers, is the ability of a moderately intoxicated person to increase his self control to some extent under conditions of stress such as those involved in being examined by a police surgeon.

The effect of alcohol on various physical and neurologic functions may be measured rather accurately under controlled conditions in the laboratory, although these precise measurements do not necessarily demonstrate the total effect of alcohol on the individual. In police cases however the examining physician must simply observe a series of signs and symptoms and then come to some conclusion as to the intoxication or sobriety of the driver.

We have attempted to correlate the apparent degree of intoxication so determined with the venous blood alcohol concentration in a series of 85 police cases. The clinical examination was based on the recommendations of the National Safety Council, and it included various practical tests of neuromuscular coordination and memory, a search for evidences of disease or injury as well as general observations of the subject and estimates as to the degree of his general orientation and emotional stability. Each such observation is not quantitative but we believe that the total impression gained by an experienced observer from a thorough examination affords a rather accurate index of the degree of intoxication.

Obviously any correlation between alcohol concentration and the degree of intoxication will depend on the criteria used in making the diagnosis. We have obtained a fairly definite impression as to the extent of various objective and subjective symptoms at different venous blood alcohol concentrations by experimental methods. These impressions as well as those obtained by a study of the literature and by our experience with trial

cases have constituted the basis of our criteria for intoxication although these criteria were undoubtedly slightly modified with increasing experience. Our diagnoses have been made conservatively in light of the fact that these were medicolegal cases and that we might be called on to demonstrate definite evidences of intoxication in court.

The diagnosis of 'intoxication' has been made at a point at which slight but definite signs of physiologic and behavior abnormalities are evidenced to a critical observer even under the watchful eye of a police officer. We believe that at this point the effects of alcohol are of such a degree of intensity as definitely to impair the ability of an individual to operate a motor vehicle with safety. This state was found to occur at a blood alcohol concentration of approximately 0.15 Gm per hundred cubic centimeters or less. This level undoubtedly is higher than the lowest point at which there is a definite impairment of ability to drive an automobile, but it is a practical level for use in medicolegal cases. In some cases there were slight outward signs of intoxication at levels as low as 0.05 to 0.07 Gm per hundred cubic centimeters, although even at this concentration the subjective symptoms were often considerable. When the alcohol level increased to approximately 0.18 to 0.23 Gm per hundred cubic centimeters, even an uncritical observer could notice such definite evidences of intoxication as slight muscular incoordination, thick speech and personality changes. The sense of time was frequently disturbed but the individual was usually rational. As the concentration continued to increase the extent and number of these changes also increased and the individuals became irrational, unsteady and confused. By the time the concentration had reached a zone of approximately 0.27 to 0.32 Gm per hundred cubic centimeters the neuromuscular incoordination resulted in a very definite staggering gait and the depressant action of alcohol was evidenced by a condition bordering on stupor. These degrees of intoxication, which were found by rather crude methods, correspond very closely with those described by Muehlberger.²

We have concluded that there is a very definite correlation between the degree of intoxication and the venous blood alcohol level, although there is some variation in the degree of intoxication of persons who have the same blood alcohol concentration. This is to be expected in view of the normal biologic variation between individuals. Another probable reason for the observed variation is the fact that each diagnosis involved the judgment of the examiner as well as his observations. Undoubtedly the accuracy of these judgments was affected to some extent not only by the effects on the driver of such factors as apprehension and injury, but also by the physical condition of the examiner at the time. Many of these drivers were examined in the early hours of the morning when the effects of a night

Chart 3.—Results obtained in the first case injured

on both driver and examiner would tend to be pronounced. In spite of the many sources of error, the blood alcohol concentration corresponded with the estimated degree of intoxication in nearly every case.

We have attempted to express this correlation mathematically by following a procedure used by Heise and Halpoin.²⁸ These investigators determined the urine alcohol content of 200 drunken drivers examined by them. They then expressed the correlation between the observed symptoms and the urine alcohol concentration in the next 26 cases by guessing the alcohol content of the urine. The average correlation between the estimated values and the values obtained by analysis of the urine was good, although there were considerable differences in several cases. We have plotted their data in chart 2.

Chart 1—Accuracy with which alcohol concentrations have been estimated. A, Heise and Halpoin using urine; B, results obtained by us in our first 26 cases using venous blood; C, results obtained in our last 31 cases using venous blood; D, results obtained in our last 59 cases using venous blood.

The data from our first 26 cases have been plotted in charts 3 and 4. It can be seen from charts 2, 3 and 4, that the blood alcohol values in the first 26 cases were estimated with approximately the same degree of accuracy as that obtained by Heise and Halpoin with urine. As the examiner acquired more experience, however, he was able to estimate the concentration with increasing accuracy. This is demonstrated in chart 5, in which the data on the remaining 59 cases are plotted. The one very low estimate was made after the examination of a man who spoke and understood English with difficulty, consequently it was nearly impossible to come to any definite conclusion as to his exact condition, so

and those in the last 31 cases is expressed mathematically in chart 4.

The results of this study indicate that, even though this series of individuals represented a wide range of ages, blood alcohol concentrations, times and drinking habits, there was a very definite correlation between the concentration of alcohol in the blood obtained from a superficial vein in the arm and the degree of intoxication. In each of the last 31 cases the variation between the apparent degree of intoxication, as represented by an estimated alcohol concentration, and the venous blood alcohol concentration was less than 30 per cent. In 71 per cent of these cases the variation was less than 15 per cent. As is to be expected, the correlation existing between the severity of the symptoms and the alcohol concentration of venous blood is considerably greater than that between the symptoms and the concentration in the urine.

SUMMARY AND CONCLUSIONS

1 The chemical determination of alcohol in properly selected specimens is of great value in the diagnosis of intoxication. It also supplies definite objective evidence for use in court.

2 The disagreement in the literature as to the correlation between the degree of intoxication and the blood alcohol concentration is at least partially due to the selection of improper material for analysis.

3 The relationship between the concentration of alcohol in urine and that in blood may vary widely in medicolegal cases. The blood alcohol concentration cannot be calculated from that of urine.

4 The estimation of the blood alcohol concentration by the use of the popular methods of breath analysis is subject to considerable error.

5 The existence of a practically constant ratio between the alcohol concentration of the blood in a superficial vein and that of the brain under the conditions usually encountered in the examination of drinking drivers is indicated by evidence from the literature. Further evidence is afforded by our observations which show the existence of a definite correlation between the apparent degree of intoxication and the venous blood alcohol concentration. This blood-brain alcohol ratio at alcoholic equilibrium is approximately 1:1 in human beings.

6 The interpretation of the blood alcohol concentration recommended by the American Medical Association, the National Safety Council and several state laws adequately expresses the correlation between the degree of impairment of the ability to operate a motor vehicle and the alcohol concentration of venous blood. It is suggested, however, that definite recommendations concerning the use and interpretations of breath and urine alcohol determinations be made only after further study. For the present, precise interpretations based on the recommended critical levels of blood alcohol concentration should be made only after the analysis of venous blood itself.

WOUND HEALING AND INFECTION
AFTER LOCAL IMPLANTATION
OF SULFONAMIDE POWDER

J ALBERT KEY, MD

ST LOUIS

The practice of implanting sulfonamide powder in the wounds of compound fractures after debridement is now well established and is a routine procedure in most hospitals in this country. However, the routine implantation of sterile sulfonamide powder in clean operative wounds for the purpose of preventing infection has not been generally adopted. It is my belief that this is the most important addition to surgical technic since the introduction of rubber gloves and I cannot understand why surgeons have not adopted the method as a routine procedure. It cannot be because they do not encounter operative infections, because I believe that under present conditions the incidence of operative infections is in the neighborhood of 5 per cent. It may be because many surgeons believe that the local implantation of the drug is dangerous or that it interferes with wound healing or that it does not reduce the incidence of operative infections.

In order to prove that the procedure is not dangerous, that it does not delay wound healing and that it does tend to lower the incidence of operative infection, I shall report in this paper all the complications which occurred in 600 consecutive cases in which sulfonamide powder was implanted in operative wounds. This series includes only clean operations in the field of orthopedic surgery and does not include cases of infection, contaminated wounds or compound fractures. All are cases which I followed after performing the operation. If the cases of other members of the orthopedic service were included the series could be enlarged, but the records of consecutive cases would be difficult to obtain and inaccuracies might result.

In February 1939 I examined some of the patients of Jensen, Johnsrud and Nelson¹ and was so impressed by their results that I immediately adopted their method of implanting sulfanilamide powder in compound fractures after debridement. Experiments were performed in an effort to determine whether or not the local implantation of the drug was harmful.² These experiments showed that sulfanilamide, sulfathiazole and mixtures of the two drugs in various proportions were well tolerated by the tissues of laboratory animals and could be implanted in wounds in joints, tendon sheaths or body cavities without danger. Unless an unnecessarily large amount of the drug was used there was no appreciable interference with the healing of the wounds.

In May 1939 I began implanting the sterile sulfanilamide powder in clean operative wounds, and data on the first 150 patients were published.³ In January 1941

sterile sultathiazole powder was substituted for sulfanilamide and this was used in 100 consecutive cases. Then sterile mixtures of the two drugs in various proportions were used in a similar series.

The series now includes over 600 cases, and the postoperative complications which occurred were three deaths, two infections, one separation of wound edges, five hematomas requiring evacuation, two hematomas evacuated and resutured, two stitch abscesses and no toxic symptoms except fever.

The three hospital deaths which occurred in the series were in no way related to the use of the drug or to infection. The first occurred in a man aged 58 with disabling osteoarthritis of the hip. An acetabuloplasty and an obturator neurectomy were performed. The convalescence was uneventful. On the eighth postoperative morning he was found dead in bed. A complete postmortem revealed only a small amount of atelectasis in the left lower lobe of the lung. The cause of death is unknown. The wounds were healing normally. The second death was of a woman aged 64 who weighed over 300 pounds (over 136 Kg.) and who had a fracture of the hip. This was reduced by the open method and nailed under general anesthesia. The postoperative convalescence was unsatisfactory in that the patient suffered with distention and nausea and did not take fluids or food well by mouth. In spite of much intravenous fluid she died on the eighth postoperative day. The postmortem revealed acute myocarditis, colitis and atelectasis in the right lung. The wound was healing normally. The third patient who died was a senile man aged 84 whose fractured hip was nailed by the open method under local anesthesia. The patient was irrational and incontinent and frequently removed the dressing from his wound. Several stitch abscesses developed along the suture line. He died in his sleep on the sixty-third postoperative day. The postmortem revealed senile arteriosclerosis and pulmonary edema. At this time his wound was healed and he was walking a little without support, as he would not try to use crutches.

The two infections were late, mild and avoidable. The first occurred in a boy aged 4 years who had a large lymphangioma removed from the thigh. He returned to the hospital eighteen days after the operation with fever and a large collection of lymph in the wound. This was evacuated by forcing a hemostat through the thin scar, and the wound healed promptly. The second occurred in a man aged 42 who suffered a severely comminuted subtrochanteric fracture of the femur. This was reduced under local anesthesia and the fragments were fixed with a Neuteld nail. A hematoma developed in the distal portion of the wound and on the fifteenth postoperative day this was evacuated and found to be infected. The infection was superficial to the deep fascia and the wound healed promptly after it was evacuated. The first infection could have been prevented by the pressure dressing which the parents were instructed to keep on and the second by an early evacuation of the hematoma.

The 2 patients with stitch abscesses were the man referred to who was irrational and incontinent after his hip was nailed and a woman who was operated on for internal derangement of the knee. The internal semilunar cartilage and an avulsed tibial spine were removed. She was permitted to walk on the fourth postoperative day and three stitch abscesses were noted two days later. The skin sutures were removed the

knee put at rest and sulfathiazole given by mouth. The deeper layers of the wound were not involved. She left the hospital on the thirteenth postoperative day with the wound healed. She stated that on five previous occasions she had had subcutaneous abscesses around this knee.

Hematomas developed in the wounds of 5 patients and some old blood was evacuated when the sutures were removed. 1. A man who had an Ober fasciotomy

Fig 1—Two wounds immediately after removal of sutures from the larger wound. Smaller biopsy wound is 16 days old and the larger wound 10 days old. The proximal third of the humerus was excised with a sarcoma and the proximal third of the fibula was transplanted to the shoulder.

developed a large hematoma, and blood clot was pressed out on several occasions after the sutures were removed. 2. A man from whom an osteoid osteoma of the tibia was removed had a rather large dead space in the wound, and some old blood was pressed out when the sutures were removed. 3. A girl aged 14 years with an old slipped epiphysis of the hip developed a hematoma in the lower end of the wound after an osteotomy of the neck of the femur and fixation with a nail. This drained for a few days after the sutures were removed. Similar hematomas occurred in the wounds of the 2 obese women with old subtrochanteric fractures which were fixed with Neufeld nails. In all of these sulfathiazole was sprinkled or pushed into the opening and the wounds healed without infection.

In 2 instances the wounds were opened on the second postoperative day and large hematomas were evacuated, clotted blood was removed and the wound was then sprinkled with sulfathiazole and sutured. Both healed without further complications. One was a lumbosacral fusion, in the other the tip of the spinous process of the first thoracic vertebra and a considerable amount of the surrounding fascia were excised in order to relieve persistent pain complained of by a woman.

In 1 instance after a lumbosacral fusion a wound was opened because of pain and fever. No infection was found. This patient developed a decubitus ulcer which

later involved the lower portion of the wound and necessitated a second operation and suture for healing.

In 1 instance the skin edges separated and the wound healed by epithelization. The patient was a young man whose clavicle had been excised the preceding year. He returned with a rather large local recurrence of the sarcoma. This was excised with the overlying skin and a rather wide area of the surrounding tissue including part of the acromion. This left a considerable dead space covered by skin flaps under moderate tension. When the pressure dressing and sutures were removed the skin margins retracted about half an inch. Sulfathiazole powder was sprinkled on the exposed hematoma, and the wound healed without infection.

It is to be noted that with two exceptions all the operations in which the aforementioned hematomas developed were done under local anesthesia with procaine hydrochloride which contained four drops of 1:1,000 epinephrine to the ounce. This technic causes the surgeon to omit the ligation of some vessels, which may bleed later. It is also to be noted that three hematomas including the one which became infected occurred after operations in which a Neufeld nail was used. This is because the fixing of the long plate attached to this nail necessitates considerable trauma to the vastus lateralis muscle.

With the foregoing exceptions all the wounds healed satisfactorily and in no longer time than would be required by similar wounds in which the sulfonamide powder had not been implanted. In most instances the sutures were removed on the sixth, seventh or eighth postoperative day. In large wounds in obese patients they were left for ten days or more. In many instances cross straps of adhesive were used to relieve the tension on the skin after the sutures were removed.

In cases in which plaster casts were applied over the wound the sutures were usually left in until the cast was removed, often several weeks later. In none of these cases did stitch abscesses or skin infections develop, because sulfonamide powder was sprinkled on the suture line before the dressing and cast were applied.

As explained in the preceding article,³ the operative technic used was not especially elaborate and silk or cotton was used for ligatures and sutures. The technic differed from that used in the past in no way except that in this series sulfanilamide, sulfathiazole or a mixture of these two powders was implanted in the wound just before it was closed.

In view of the experience reported in this paper it is in order to mention a recent paper by Bick⁴ in which he reports clinical observations on the healing of 50 traumatic and operative wounds. He states that "there was no question but that wound healing was delayed when powders were implanted locally" and "the delay was considerable, representing on the average between 50 and 75 per cent of the time factor." He further stated that the scar of the treated group remained broader at equivalent intervals than did the scars of the controls and that the delay in healing caused longer hospitalization and postpones necessary active motion and massage.

In answer to the foregoing, I believe that Bick used too much powder in a given wound or distributed it improperly. Also the daily inspection did not help

4 Bick, E. M. Observations on Topical Use of Sulfonamide Derivatives, J. A. M. A. 118:511-513 (Feb. 14) 1942.

the healing On the day on which Bick's paper was called to my attention 2 patients had their sutures removed These were photographed (figs 1, 2 and 3) and I believe that their appearance is typical of the wounds of this series and is approximately the same as that of similar clean wounds without the local implantation of sulfonamide powder In following the 600 cases reported in this series I have noted no difference between the scars and those in other cases in which similar operations were performed in the past and sulfonamide powder was not implanted in the wounds

In regard to hospitalization, this period was not lengthened but was often shortened, as many patients were permitted to go home earlier than usual because of the added factor of safety from infection obtained by the implantation of a sulfonamide compound in the wound This is particularly true of out of town patients (fig 3) The diagnosis, type of operation, highest temperature, days in the hospital and character of the healing of the wounds in the first 150 cases in this series are given in the preceding paper on this subject³ Repetition of the data on the entire series would needlessly lengthen this paper

METHOD AND CHOICE OF DRUG

Since the drug is not bactericidal it should be sterile when it is placed in the wound Sterile packages containing 5 Gm each of sulfanilamide or of sulfathiazole or of a mixture of the two can be obtained from many drug houses Or the drug can be sterilized in glass tubes or bottles by autoclaving at 18 pounds pressure for twenty minutes This method will not kill all spores, as the bottles are stoppered with gauze and paper, but it has proved satisfactory in some hundreds of cases

In wounds contaminated with staphylococci, sulfathiazole is the drug of choice, but in clean wounds sulfanilamide is equally satisfactory On theoretical grounds I prefer a mixture of two parts of sulfanilamide and one part of sulfathiazole in clean wounds In the first 150 cases of this series sulfanilamide was used, in the next 100 cases sulfathiazole was used, and in the next 100 cases various mixtures of the two drugs were used There was practically no difference in the results

Fig 2—Leg wound of same patient ten days after operation immediately after removal of the sutures.

The two infections occurred in wounds in which sulfanilamide was used, but, as has been explained, these infections occurred long after the drug had disappeared from the tissues and could have been prevented by proper after-care I prefer the mixture but do not hesitate to use either of the drugs alone if the mixture is not available

There has been some discussion about the form of the drug I have used a fine powder, fine crystals and rather coarse crystals and find no difference in the results It is soon dissolved in the fluid in the wound unless it is permitted to form aggregates or lumps The crystals flow more easily but are heavier and do

Fig 3—Sutures in place four weeks after operation The radial nerve was sutured and a step-cut operation was done for nonunion of the humerus Patient left hospital on the fourth postoperative day in a hanging cast.

not cover as much surface per gram A sterile salt shaker containing 5 Gm of the drug is on the instrument table and this is enough for most operations, and a little is saved to sprinkle along the suture line after the wound is closed Usually a good deal is left in the shaker Occasionally in extensive incisions part of a second 5 grams is used The powder is sprinkled over the surface and is then smeared with the fingers so that no aggregates are left and the drug reaches the entire area of the wound In large joints a gram or more is dropped in the joint and smeared around a bit before the synovial surface is closed After the subcutaneous sutures are tied the skin margins are wiped with the finger to remove any excess of the drug

Not over 10 Gm has been used in any clean wound As no toxic symptoms other than fever have been noted in any of the patients, no record is kept of the exact amount of drug implanted nor is the blood level of the drug determined A postoperative elevation of the temperature to 38.6 F occurred in approximately 5 per cent of the patients Whether or not this was caused by the drug I do not know At any rate it subsided quickly and did no harm Rashes have occurred in some patients who were also taking the drug by mouth and one such patient had hematuria These patients had osteomyelitis and were not included in this series

SUMMARY

The local implantation of sulfonamide powder in the clean operative wounds is a safe procedure and lowers the incidence of operative infections In 600 cases

consecutive cases there were no toxic symptoms, except fever, which occurred in about 5 per cent of the cases and may or may not have been caused by the drug. In these cases the total postoperative complications were 3 deaths, 7 hematomas, 1 separation of wound margins, 2 stitch abscesses and 2 infections. The 2 infections were mild and developed late. In the other cases the wounds healed in a normal manner without excessive scar formation and the average period of hospitalization was shortened by the use of the drug. Sulfanilamide or sulfathiazole powder or crystals or a mixture of the two drugs is suitable. An excessive amount of the drug may delay the healing of the wound.

Since the drug is not bactericidal it should be sterilized before it is implanted in clean operative wounds.

In view of the favorable results reported in this paper, I believe that the practice of implanting sulfonamide powder in clean operative wounds should become routine in all civilian and military hospitals. This is especially true at this time when, owing to the emergency resulting from the war, so much surgery must be done under abnormal conditions and the incidence of operative infection may be expected to be unusually high.

PHENOTHIAZINE

EXPERIMENTAL AND CLINICAL STUDY OF TOXICITY AND ANTHELMINTIC VALUE

Z. BERCOVITZ, M.D.

R. C. PAGE, M.D.

AND

E. J. DE BEER, Ph.D.

NEW YORK

Our interest in phenothiazine as an anthelmintic agent was stimulated by Manson-Bahr's report¹ on its effectiveness in threadworm and roundworm infections in man. An additional stimulus was provided by the preliminary report of the Council on Pharmacy and Chemistry,² which stated that phenothiazine³ had interesting possibilities and that further investigations would be useful for a proper evaluation of its therapeutic value. Our studies have shown that phenothiazine is not an effective anthelmintic and in human beings and in rats is capable of causing toxic reactions.

Our program of study was divided into three categories: (1) an experimental study on rats, (2) blood and urine studies in human beings and (3) a study of phenothiazine as an anthelmintic.

CHRONIC TOXICITY STUDY IN RATS

A chronic toxicity study of the effects of repeated oral doses of phenothiazine was carried out as follows. Two groups of 10 male albino rats each were maintained on a diet of ground Purina Dog Chow. Sufficient drug was mixed with the diet of one group to make it 0.5 per cent with respect to phenothiazine content. The other group served as a control group. The experiment was continued for eighteen days. The total drug consumed per rat averaged 1,420 mg, or 390 mg per kilogram per rat.

The treated animals were unkempt and depressed and apparently excreted the drug or its degradation products in the urine, as was shown by the magenta colored spots which were found on the paper under the cage.

At the end of the experiment the animals were killed and examined. No gross pathologic lesions were found. Microscopic examinations of the essential organs including the bone marrow, were made. Examination of the bone marrow revealed hypoplasia of all cellular elements in 1 rat and normoblastic hyperplasia in another. The latter is generally regarded as evidence of peripheral blood destruction. Sections of the livers, spleens, kidneys, gastrointestinal tracts, adrenals and brains were without any significant changes from the normal controls.

HUMAN TOXICITY STUDY

Twenty-four patients attending an outpatient clinic were studied during a course of phenothiazine. These patients had long standing diseases such as chronic ulcerative colitis and lymphogranuloma venereum or had intestinal infections with various helminths or protozoa. None of the patients treated had acute infections, so that for the purpose of this study we can reasonably assume that any significant changes in blood or urine during phenothiazine therapy were due to phenothiazine and not to the disease. A complete blood count and urinalysis were made before therapy was begun and were repeated twice weekly while the patient was receiving phenothiazine and once or more times after the drug was stopped.

A full course of phenothiazine for an adult consisted in giving $1\frac{1}{3}$ Gm three times daily for ten days, making a total of 40 Gm.

Results of red blood cell counts were as follows. Six patients had no decrease in their counts during or at the end of therapy, 11 patients had a decrease in red blood cell count up to 500,000 per cubic millimeter, 4 had a decrease of from 500,000 to 1,000,000 per cubic millimeter and 3 had a decrease in red blood cells of more than 1,000,000. During therapy, examination of the blood smears frequently showed anisocytosis and poikilocytosis, and erythroblasts were found in one smear.

The hemoglobin of 23 patients was studied before, during and after phenothiazine therapy. Five patients had no decrease in hemoglobin, 9 patients had a decrease of less than 10 per cent and 9 patients had a decrease of more than 10 per cent in hemoglobin.

Repeated urinalyses on 23 patients undergoing phenothiazine therapy revealed that 13 showed no abnormal constituents during therapy, 6 developed a trace of albumin, 1 developed a considerable amount (3+). Two patients showed cylindroids during therapy and 1 showed hyaline and cellular casts. Crystals of an undetermined nature that polarized light were found in the urine of 1 patient. The urine was a brownish red mahogany color while the drug was being taken.

Complete white blood cell counts were not significantly altered in any of the patients during or after therapy except for the finding of an occasional myelocyte in the smears of 2 patients and metamyelocytes in the smear of 1 patient.

³ Phenothiazine was furnished through the courtesy of Burroughs Wellcome & Co (U S A) Inc New York.

Side effects of nausea and vomiting were manifested by 2 patients and nausea alone by 1, the amount of phenothiazine taken in these cases was 6 Gm, 18 Gm and 40 Gm respectively

EFFECT ON INTESTINAL PARASITES

Private patients and patients attending an outpatient clinic were studied. These patients had a variety of intestinal parasitic infections and they were all given a course of phenothiazine in order to determine if this drug is therapeutically effective as an anthelmintic in infections caused by intestinal parasites. Study, therefore, was not made on any one type of infection but rather on a cross section of parasitic intestinal infections. The results are summarized in the table.

The usual dose schedule in this study of phenothiazine was as follows: for children 2 to 6 years of age $\frac{3}{4}$ Gm twice daily for ten days (13 Gm total), for children 6 to 12 years of age $\frac{3}{4}$ Gm three times daily for ten days (20 Gm total), for adults $1\frac{1}{4}$ Gm three times daily for ten days (40 Gm total). In some of the patients this

* In one case after treatment with oleoresin of aspidium the head was obtained

course of treatment was repeated after a rest period of two weeks. The results are summarized in the table and are detailed as follows:

Enterobius vermicularis (pinworm). Ten patients with pinworms were treated with phenothiazine. The total dose for children ranged from 13 to 25 Gm and for adults from 25 to 100 Gm. The criteria for cure were three negative NIH swabs. Eight cases remained positive after treatment. Two were considered cured of the infection.

Hookworm. Three adult patients with hookworm infection were treated with total doses ranging from 28 to 93 Gm; all remained positive after the course of treatment.

Ascaris lumbricoides (roundworm). Two patients with roundworms were each given a total of 40 Gm of phenothiazine; ova were present following treatment.

Taenia saginata. One patient was given a total of 30 Gm of phenothiazine; the head of the worm was not recovered. Following this oleoresin of aspidium was given and the head obtained. Another patient was given a total of 93 Gm and the worm head was not obtained.

Schistosoma mansoni. One patient with this infection was given a total of 58 Gm; the stool remained positive.

Trichuris trichiura (whipworm). Nine patients with whipworm were treated with phenothiazine with total doses ranging from 13 Gm in a 2 year old child to 93 Gm in 1 of the adults. In all cases ova were found in stool examinations following treatment.

Endameba histolytica. Three patients with this ameba in the stool were treated with phenothiazine in total doses of from 6 to 30 Gm. On subsequent examination 1 of the 3 had three negative stools following a total of 10 Gm.

Endameba coli. Seven patients harboring this organism were treated with total doses ranging from 8 to 40 Gm and all cases remained positive following treatment.

Giardia lamblia. Three patients harboring this flagellate were treated with total doses ranging from 13 Gm (2 year old child) to 28 Gm in an adult; stools of all 3 remained positive.

Iodameba buetschlii. Two patients were given a total of 36 Gm (child of 8) and 40 Gm (adult) respectively of phenothiazine; stools of both were positive following treatment.

Diandameba fragilis. One patient with this amebic infection was given a total of 68 Gm, after which the stool still remained positive.

Endolimax nana. One patient with this infection was given a total of 68 Gm; the stool remained positive.

SUMMARY AND CONCLUSIONS

1. The effects of repeated oral doses of phenothiazine were studied on rats. The only abnormal findings on microscopic examination of the essential organs were hypoplasia of all cellular elements in the bone marrow of 1 rat and normoblastic hyperplasia of the bone marrow in another.

2. Blood and urine studies during courses of phenothiazine therapy in 24 human beings showed a decrease of more than 1,000,000 red blood cells per cubic millimeter in 3 cases; a decrease of more than 10 per cent in hemoglobin in 9 patients; a trace of albumin in the urine of 6 patients and a pronounced amount in 1 patient; cylindroids in 2 patients and hyaline and cellular casts in 1 patient. Two patients developed nausea and vomiting.

3. Forty-four patients with intestinal parasitic infections of various types were treated with phenothiazine. Only 3 could be classified as being clinically cured. Of these 3, 2 had pinworm infections and the other an *Endameba histolytica* infection.

4. From our clinical and experimental study of phenothiazine in human beings and rats it appears that this drug is capable of causing toxic reactions in an appreciable number of patients.

5. It was not an effective anthelmintic or amebicide in the patients studied.

Hypnotism—Genuine hypnotism actually stands in the same category as chemistry, physics or mathematics. It is based on definite basic laws and principles which have been discovered by patient experiment and research and just as astronomy has evolved from the superstitions of astrology and chemistry from the medieval search for the magical philosopher's stone, so hypnotism has evolved from the mesmerism of the eighteenth and nineteenth centuries into a true science, a branch of the great subject of the human brain and human consciousness. The main facts and rules on which the science of hypnotism are based are known to all competent students of the subject just as the general laws of chemistry are known to chemistry students.

There can be no doubt that hypnotism may be of great aid in curing many types of human disease. At the present moment, however, it has practically no real value in America. This is due entirely to popular prejudice, that curious quirk in human thinking which sees in hypnotism something closely allied to black magic and the supernatural. We must not blame the medical profession for our own ignorance and superstition rob them of this very valuable device or combat human ailments. First we must educate ourselves. We will then find that the doctor is the most easily educated of all humanity.—Estabrook, G. H., professor of psychology at Colgate University, Hypnotism, New York, E. P. Dutton & Co., Inc., 1943.

ACUTE TYPHOID CHOLECYSTITIS

A DANIEL RUBENSTEIN, M.D.

BOSTON

Acute cholecystitis may be of typhoid origin. The failure to detect this association may result in grave consequences. Because of the relative infrequency of typhoid and its complications in modern medical practice, one rarely thinks of this disease when confronted with a case of acute cholecystitis. This report reviews 4 cases of acute typhoid cholecystitis to reemphasize the importance of this complication of typhoid. Two of the 4 cases came to operation before the association with typhoid had been established. In 2 instances secondary attacks occurred among the personnel of the hospitals to which the patients had been referred for operative procedures.

The localization of the typhoid bacillus in the gallbladder during the course of typhoid has become common knowledge since the report of Gilbert and Girode¹ in 1890. Chiari² in 1894 recovered this organism from the gallbladder in 19 out of a total of 22 cases of typhoid which came to postmortem examination. Nevertheless, clinical evidence as to the invasion of the gallbladder is demonstrated by a comparatively small percentage of cases of typhoid. Holscher³ observed gross changes in the gallbladder in only 5 out of 2,000 postmortem examinations performed in cases of typhoid. Keen⁴ in 1898 recorded 30 cases of typhoid cholecystitis. In 1907 Thomas⁵ collected 154 cases of typhoid complicated by acute cholecystitis. In 39 of these perforation of the gallbladder occurred. In the following year Ashurst⁶ reported 21 operative cases of acute typhoid cholecystitis. Since 1916, although foreign reports have been quite numerous, references to this condition have been infrequent in the English and American literature.⁷ With one exception⁸ the reported cases have been concerned primarily with acute typhoid cholecystitis in children.

In 1920 Reid⁹ made the observation that pain and tenderness in the right upper quadrant associated with slight muscle spasm may be encountered during the course of typhoid. In most cases the symptoms of gallbladder involvement subside without the necessity of surgical intervention. When, however, the damage to the gallbladder is more extensive, surgery may become necessary. In such cases a definitely distended gallbladder is usually found at operation.

The signs and symptoms of acute cholecystitis may become manifest during the course of typhoid or after convalescence has been established. In the majority of cases they are first noted after the second week of

the fever. Exceptionally the gallbladder complication appears at the very onset of the underlying disease. Panayotatou¹⁰ reported a case of primary typhoid cholecystitis in 1920. A similar report was made by Muscio-Fournier and his associates¹¹ in 1928.

Perforation of the gallbladder is a serious end result of acute typhoid cholecystitis. Liege and Folliasson¹² in 1931 reviewed 35 published reports of cases in children. These authors remarked on the frequency of perforation in their series. This outcome occurred in 16, or 46 per cent, of the entire group. In several of their cases it was noted that evidence of perforation was found only a few hours after the onset of clinical signs of gallbladder involvement. Emphasis is placed on the necessity for operative intervention in perforated cases. Failure to operate results in 100 per cent mortality. Salmon¹³ reported a case of acute eberthian cholecystitis associated with biliary peritonitis. At operation, although the gallbladder was large and distended, no visible break could be detected in the wall.

Statistical studies indicate that jaundice is one of the rarest complications of typhoid. Only 52 cases were recorded by DaCosta.¹⁴ McRae¹⁵ noted only 8 cases in a series of 1,500. The cause of the icterus associated with typhoid is variable. Jaundice may be one of the signs associated with acute typhoid cholecystitis. However, all jaundiced cases of typhoid do not necessarily show gallbladder damage. Petridis¹⁶ reported a case of fatal typhoid in which the jaundice appeared at the very onset of the illness. The icterus in this case was not associated with gallbladder disease but seemed rather to have been the result of a diffuse hepatitis. Berry¹⁷ reported a case of typhoid with icterus and thrombocytopenic purpura. Autopsy revealed no gallbladder involvement. Hence it is obvious that the presence of jaundice in a case of typhoid need not necessarily be indicative of a complicating acute cholecystitis.

REPORT OF CASES

CASE 1¹⁸—Dr. R. S., a house officer aged 25, married, was admitted to the medical service of his own hospital on Dec. 16, 1941, with complaints of malaise, generalized pains and aches and fever. He had been perfectly well until three days prior to admission, when he had noticed that he tired easily. The temperature at this time was normal. In twenty-four hours the patient became aware of generalized pains and aches associated with slight soreness of the throat. On the following day, when it was found that the temperature was elevated, he was admitted to the hospital. On admission physical examination was essentially negative except for diffuse redness of the throat.

Examination of the blood showed a red cell count of 5,700,000 with a hemoglobin content of 96 per cent, and white cell counts varying from 3,500 to 7,300, the blood smear showed 69 per cent neutrophils, 20 per cent lymphocytes, 10 per cent

18. This epidemiologic investigation has been reported in detail.

mononuclears and 1 per cent cosmophils. Urinalysis was negative. The blood serum agglutination reactions against typhoid showed a gradual rise in titer from 1 plus in a dilution of 1:40 on December 17 to 2 plus in 1:320 on January 6. A blood sample submitted for a Widal test to the state laboratory was reported positive on December 30. A stool culture was positive for *Escherichia typhosa*.

The temperature remained elevated for about ten days. The course was mild and uneventful except for an attack of acute pain in the right upper quadrant on December 25. The pain was severe and radiated to the right part of the back and the right side and was relieved only after the administration of morphine. The attack was associated with spasm over the region of the gallbladder. Tenderness in the right upper quadrant persisted for five days. The temperature became normal on the eleventh hospital day. There was no recurrence of gallbladder symptoms. The diagnosis was typhoid fever, acute typhoid cholecystitis.

CASE 2¹⁸—Mrs. S. R., a housewife aged 28, was admitted to the hospital on Dec. 6, 1941, with the chief complaint of pain in the right upper quadrant of one day's duration. About three weeks before admission, a severe infection of the upper respiratory tract associated with 'heaviness of the chest' and productive cough appeared. About a week later the patient noticed that she tired more easily than usual. Her arms and legs felt heavy. She could scarcely stand on her legs. After this feeling of tiredness had persisted for about a week she found that her temperature was 104° F. She consulted a physician who advised bed rest. The fever persisted. On December 1 she became aware of a dull ache in the right upper quadrant. This subsided until twenty-four hours prior to admission when the pain returned with increasing severity. It was intense and colicky and radiated to the back. She became nauseated and vomited several times. There was no jaundice and no clay-colored stools. The past history revealed an attack of pain in the right upper quadrant one year previously which had lasted for three days.

On admission the temperature was 103.4° F. and the pulse rate 120. On physical examination the patient was alert, feverish and restless and in obvious distress. General examination was otherwise negative except for spasm and tenderness in the right upper quadrant. Examination of the blood showed a white cell count of 8050, a red cell count of 4,130,000 and a hemoglobin content of 70 per cent. Urinalysis was negative. The icterus index was 11.

On December 7 the gallbladder was removed under spinal anesthesia. It was tense, edematous and inflamed, with several small areas of necrosis. No stones were found.

Following operation, the patient had a spiking temperature. On December 9, two days after operation, the white cell count was 9000. The temperature on that day was 101.4° F. The temperature gradually subsided and was normal on December 24. Except for the temperature, the course was uneventful and the patient was discharged on December 27.

On January 21, about six weeks after operation, the Widal reaction was found to be positive. *E. typhosa* was recovered from the stools at the same time. The diagnosis was typhoid fever, acute typhoid cholecystitis.

CASE 3—Miss L. B., aged 29, white, was admitted to the hospital on July 12, 1936, with the chief complaint of pain in the right upper quadrant. She had been perfectly well until July 1 when she noted onset of a severe frontal headache. Her physician found that she had a temperature of 102° F. Several days later she began to have severe chills at irregular intervals for about forty-eight hours. Two days prior to admission there was sudden onset of sharp crampy pain in the right upper quadrant radiating at times to the right shoulder. There was persistent anorexia, nausea and intractable vomiting. One day prior to admission there appeared a profuse diarrhea which lasted for several days. The sharp pain was intermittent, leaving a dull constant ache. There was no past history of any gastrointestinal symptoms. The patient had never been jaundiced in the past.

Physical examination showed that the patient was well developed and well nourished and was in obvious distress. The temperature was 102° F., the pulse rate 104. Positive physical

findings were limited to the abdomen, which showed decided hyperesthesia, spasm and tenderness in the right upper quadrant. The gallbladder could not be felt. Laboratory examination on July 12 showed a white cell count of 25,500. Urinalysis was negative except for a few granular casts in the sediment. A flat plate of the gallbladder region showed no evidence of stones. The gallbladder could not be outlined.

Operation was performed on July 13, one day after admission. A large distended gallbladder was found, matted down to the liver bed by adhesions. The liver appeared slightly enlarged. The gallbladder was acutely inflamed and surrounded by heavy plastic exudate. Cholecystectomy was performed. Following operation the temperature remained elevated, spiking between 99 and 103° F. for ten days. During the course of the succeeding six days it subsided gradually and became normal on July 29, seventeen days subsequent to admission and twenty-eight days after the onset of her illness. The white cell count postoperatively varied from 7,100 on July 15 to 9,600 on August 1. The blood smear on August 1 showed 54 per cent neutrophils, 39 per cent lymphocytes and 7 per cent monocytes. The red cell count was 3,480,000. On July 17 the Widal reaction was reported positive for typhoid. A positive stool culture for *E. typhosa* was obtained on August 11. Following the subsidence of the temperature recovery was uneventful. The patient was discharged on August 11. The diagnosis was typhoid fever, acute typhoid cholecystitis.

Following discharge from the hospital the stool cultures continued to be positive. When this condition persisted for one year from the onset of the illness the patient's name was added to the carrier list. To cure the carrier condition cholecystectomy was performed in April 1938. Laboratory data subsequent to this operation finally indicated that the patient had been relieved of the carrier state. The patient's name was therefore removed from the carrier list.

CASE 4—Miss A. H., aged 29, white, was admitted to the hospital Sept. 16, 1938. She had been well until September 11 when there was onset of persistent cough, headache and fever. There was no past history of any similar illness. There was no history of any previous gastrointestinal symptoms. On admission the temperature was 102.2° F., pulse rate 108 and respiratory rate 16. Physical examination was entirely negative. Laboratory examination revealed a red cell count of 3,400,000 and a white cell count of 9,600. The smear showed 85 per cent polymorphonuclears and 15 per cent lymphocytes. Urinalysis was negative.

The temperature remained elevated. On September 19 the patient felt somewhat improved in spite of the high temperature. On September 22 diarrhea was noted for the first time. Her condition became aggravated and she became listless and disoriented. Five days later, September 27, she began to complain of headache and occasionally of abdominal pain. Because of her mental condition the pain was difficult to localize. On October 3 it had increased in severity, and apparently an ice bag gave some relief. A chest plate at this time was reported as within normal limits. For the next ten or eleven days the patient continued to have intermittent abdominal distress and physical examination remained essentially negative. The temperature thus far during the entire hospital stay had remained consistently elevated. The pulse in general was slow for the height of the fever.

On October 18 the abdominal pain seemed to have become particularly intense. At that time a Widal reaction was reported as positive. The following day muscle spasm was noted in the right upper quadrant. A diagnosis of acute cholecystitis was made and operation was considered necessary. The white cell count which had varied from 7,000 to 10,200 until October 8 rose to 15,400 on October 17 and to 23,600 on October 19. At operation an acutely distended gallbladder was found with thickened and edematous walls. The gallbladder was drained. *E. typhosa* was cultured from the bile recovered from the gallbladder at the time of operation and on several occasions from the stools. The temperature gradually subsided during the week following operation. There was profuse drainage of bile through the operative wound. The patient was discharged from the hospital on Jan. 14, 1939.

Bile continued to drain through a persistent sinus at the operative site. The diagnosis was typhoid fever, acute typhoid cholecystitis.

Following operation, the stool cultures and drainage from the biliary fistula were consistently positive for *E. typhosa*. When this condition persisted for several months it was obvious that the patient had become a chronic typhoid carrier. In August 1939, approximately eleven months subsequent to the onset of her illness, cholecystectomy was performed to relieve the carrier state. At operation the gallbladder was found "adherent to the abdominal wall beneath the sinus tract at the lower end of the previous incision. It was markedly dilated and thickened, and contained at least one stone." Culture of the bile at this time was again reported as positive for *E. typhosa*. Following cholecystectomy the typhoid bacilli rapidly disappeared from the stools. Release specimens submitted during an observation period of one year were consistently negative for *E. typhosa*. The carrier condition had been relieved.

COMMENT

In 3 of the 4 reported cases, the severity of the clinical picture was of such intensity as to warrant operative intervention. It is obvious that the risk of perforation justifies surgical measures in any case in which such an eventuality is at all likely.

It is noteworthy that 2 of these patients (2 and 3) underwent operation before the association with typhoid had been established. A nurse who had been attending patient 2 and who had frequently handled postoperative dressings came down with typhoid. The typhoid etiology of the source case was determined only by the epidemiologic investigation which was instituted when the nurse's infection was reported to the state health department. Patient 3 contracted typhoid during the course of a small epidemic. The presence of other cases of typhoid in the wards of the hospital to which she had been admitted for surgical treatment first called attention to a possible diagnosis of typhoid. Although A. H. (patient 4) had been diagnosed as having typhoid before operation, a student nurse who had been caring for her came down with the disease before this diagnosis had been made.

This series of cases is indicative of the risk which the undiagnosed case of typhoid may bring to bear on employees in medical and surgical wards in hospitals. Such incidents are particularly liable to occur in connection with cases of acute typhoid cholecystitis in which signs and symptoms of the acute gallbladder involvement are often so striking as to obscure the underlying disease. Furthermore, it has been observed¹⁹ that hospital personnel may contract typhoid subsequent to contact with previously undiscovered typhoid carriers admitted to hospitals for operations on the gallbladder. Although the chronic cholecystitis associated with the typhoid carrier state has been definitely established as a clinical entity, this fact may be forgotten by the physician confronted with a case of chronic gallbladder disease. Hence attention must be given in all cases of both acute and chronic cholecystitis to the possibility that *E. typhosa* may be the causative agent.

It is of interest that 2 of the patients (3 and 4) became chronic typhoid carriers. The carrier state in both instances persisted until cure was brought about by cholecystectomy. There is a possibility that S. R. (patient 2) might also have become a carrier had cholecystectomy not been performed. Stool cultures submitted by R. S. (patient 1) have been positive five

months subsequent to the onset of his illness. Garbat²⁰ reported that a large percentage of patients with typhoid complicated by acute cholecystitis tend to become permanent carriers. It is therefore doubly important that all patients with acute typhoid cholecystitis submit a sufficient number of release specimens in order to exclude the development of the carrier state. On the other hand, acute cholecystitis is not the only factor that predisposes toward acquiring the carrier state. Very few known carriers present a past history of typhoid complicated by acute cholecystitis.

Analysis of these cases reveals that in each instance the complicating acute cholecystitis was preceded by a period of unexplained fever. A similar interval of idiopathic hyperpyrexia antedating the acute cholecystitis is noted in many of the cases recorded in the literature. Hence a diagnosis of typhoid must be considered in any case of acute cholecystitis in which the history reveals that the onset of gallbladder symptoms was preceded by a period of unexplained fever without any other localizing signs.

Occasionally the acute cholecystitis may appear within a few days following the recovery from typhoid. These cases may be considered in the same category with those in which the gallbladder involvement occurs during the course of the underlying disease. However, as the interval between the typhoid and the onset of gallbladder symptoms is prolonged, it must be assumed that chronic inflammatory changes arise within the gallbladder. The pathologic condition in such cases becomes that of chronic rather than of acute cholecystitis. Chapuy²¹ reported a case of acute typhoid cholecystitis unassociated with any illness which might have been regarded as typhoid. It must be borne in mind that approximately one third²² of known typhoid carriers do not present a past history of typhoid. It would therefore be extremely difficult to prove that Chapuy's case was actually acute typhoid cholecystitis rather than the chronic cholecystitis of a typhoid carrier presenting an initial attack of gallbladder disease. The finding of gallstones at operation may in such cases assist in establishing a diagnosis of chronic cholecystitis. In the series of cases of chronic typhoid cholecystitis reported by Bigelow and Anderson²³ in 1933, gallstones were found in all. No stones were found in any one of our 3 cases of acute cholecystitis in which surgical treatment was undertaken. Similarly, those reporting in the literature rarely if ever mention the finding of gallstones at operation.

Consideration must be given to the protection of hospital personnel against chance contact with cases of unrecognized typhoid cholecystitis. Several procedures are available as safeguards for such persons. Patients with chronic cholecystitis presenting a past history of typhoid or any unexplained fever, no matter how long ago, should be placed on typhoid precautions until the carrier state has been excluded. In addition, great care must be exercised by persons handling dressings and discharges from all other patients with gallbladder disease. Cases of acute cholecystitis with a history of a preceding bout of unexplained fever should be investigated by suitable laboratory methods as probable cases of typhoid. Furthermore, routine antityphoid immuni-

zation of hospital personnel, including nurses, physicians and ward attendants, will mitigate considerably the risk of acquiring the disease as a result of contact with patients with undiagnosed typhoid or with unrecognized typhoid carriers. To maintain a proper level of immunity, the initial three doses of vaccine must be fortified by an annual stimulating dose of 0.5 cc subcutaneously or 0.1 cc intradermally.²⁴

SUMMARY

Acute cholecystitis as a complication of typhoid may appear during the course of the disease or early in convalescence. Any case of acute cholecystitis in which the onset of gallbladder symptoms is preceded by a bout of unexplained fever should be studied as a possible case of typhoid.

Chronic cholecystitis is a frequent result of the localization of the typhoid bacillus in the gallbladder of typhoid carriers. Every patient with gallbladder disease who has a definite or suggestive history of typhoid should be placed on typhoid precautions until laboratory study excludes the carrier state.

These measures will prevent possible infection of hospital personnel from contact with patients with undiagnosed typhoid and with unrecognized typhoid carriers.

Routine immunization of hospital personnel against typhoid will also minimize this hazard.

Clinical Notes, Suggestions and New Instruments

AMPHETAMINE SULFATE POISONING IN A CHILD OF TWENTY MONTHS

HAROLD A. ROSENBAUM, M.D., CHICAGO

It seems trite to caution parents to keep drugs out of the reach of children.

The mother of a girl of 20 months was being treated with a 1 per cent amphetamine sulfate solution used as a nasal spray. There was no caution on the label that this might be toxic if taken internally.

At 3:30 p.m., before the parents realized what was happening, the child had worked off the top of the container and had drunk a quantity of the contents of the bottle. Early in the evening the child began to be increasingly restless, moving her arms and legs incessantly and crying out. She refused everything by mouth and vomited twice during the evening. I saw her at 11 p.m. and gave her 1½ grains (0.1 Gm.) of secalinal rectally. After an hour the child slept thirty minutes and then awakened and continued her former extreme activity.

At 2 a.m. she was again given 1½ grains of secalinal and after about forty minutes she slept until 6 a.m. and woke up as restless as before. When again seen at 9 a.m. her activity was extreme and there were signs of exhaustion with rapid pulse, pallor, rapid shallow respiration, hollow eyes and acetone breath. She was taken to the Children's Memorial Hospital and given 300 mg. of avertin with amylene hydrate and 300 cc. of 5 per cent dextrose and saline solution intravenously. The intravenous dextrose and saline solution was repeated early in the afternoon. At about 5 p.m. she woke up and seemed quite herself and made an uneventful recovery. She was sent home the following morning.

This report is written to call attention again to the importance of locking away from children all drugs and also to urge manufacturers to label products that can do harm.

FATAL AORTIC ESOPHAGEAL FISTULA FROM A SWALLOWED FISHBONE

REPORT OF A CASE AND REVIEW OF THE LITERATURE

LIEUTENANT R. STANLEY BANK
MEDICAL CORPS, ARMY OF THE UNITED STATES

Reports have appeared of fatal hemorrhage resulting from a foreign body in the esophagus. The case presented here emphasizes the need for early esophagoscopy in cases in which a foreign body in the esophagus is suspected. Chevalier Jackson has stated 'Esophagoscopy is demanded in every case in which a foreign body is known to be or suspected to be in the esophagus.' To this dictum might be added only the word 'early.'

REPORT OF CASE

History.—C. S., a Negro girl aged 12 years, was admitted to the medical service of the Jersey City Medical Center on Jan. 16, 1939. She had excruciating pain in the lower sternal and left interscapular areas. The past history and family history contained nothing significant. The present illness began January 6 when, during a meal which included fried fish, the patient complained of a sticking sensation in the midsternal region. The pain increased in intensity but did not radiate. It lasted three days during which the patient felt worse on ingestion of anything except cold liquids. On swallowing the patient localized the pain above the xiphoid cartilage. A physician was called and symptomatic treatment is said to have been given. At the end of the third day the pain disappeared and swallowing again became normal until January 13 when the patient again began to complain of severe midsternal pain of a sticking character, this time radiating to the left interscapular region. The dysphagia returned and fever was noticed. Late January 13 the patient became nauseated and vomited about a cupful of dark red blood containing several clots. After this her stools were constantly tarry. The physician was called again and cold liquids, bed rest and opiates were ordered. The fever became higher and the pain so agonizing that hospitalization was ordered on January 16.

Examination.—On admission the temperature was 104.2 F., respiratory rate 32 and pulse rate 150 a minute and the blood pressure 120 systolic and 60 diastolic.

The patient was well nourished and well developed; she appeared acutely ill and was writhing about in severe pain. The skin was hot and dry. The organs of the head and neck presented no abnormality. There was no cervical rigidity. Except for sinus tachycardia the heart was apparently normal. The lung fields were clear to percussion and auscultation. Hyperesthesia to light touch was present in the left interscapular region. Examination of the abdomen revealed slight deep epigastric tenderness and slight muscle spasm in the upper part of the abdomen. The organs were not palpable and there was no discernible fluid or distention. The hymen was intact. There was no vaginal discharge. The extremities were normal. Kernig's sign was not present. The deep reflexes were hyperactive and equal.

The urine showed a slight trace of albumin; otherwise it was normal. A blood count showed 4,800,000 red blood cells, 80 per cent hemoglobin (Sahli) and 17,800 white blood cells with polymorphonuclear neutrophils 84 per cent, lymphocytes 12 per cent and large mononuclears 4 per cent. A vaginal smear was negative for gonococci. Blood culture was sterile at five days. The Wassermann reaction was negative. X-ray examination of the chest revealed that the bony framework was normal. The trachea was in the median line. The heart shadow was within normal limits. Just below the clavicle at the arch of the aorta on the right there was a soft tissue shadow which may have been from the aorta itself or from a mediastinal gland. The lung fields were normal. The hilar glands were moderately enlarged and there was some basal thickening of the pleura.

Diagnosis and Course.—The clinical impressions were perforation of the esophagus by a fish bone, mediastinitis and hemorrhage, probably due to erosion of an esophageal vessel. We felt that esophagoscopy was contraindicated at the late date at which

²⁴ Longtellow, D. and Lippold, G. F. Typhoid Vaccine Studies: Revaccination and Duration of Immunity. *Am. J. Pub. Health* 30: 1311 (Nov.) 1940.

the patient was seen by us. It was hoped that the mediastinal infection would localize and that the hemorrhage was sufficiently slow to arrest itself spontaneously. A conservative plan of therapy was therefore decided on. Pam was relieved with repeated small doses of morphine sulfate. Alcohol sponges were given and cold fluids were administered by mouth. The patient's condition remained unchanged except for a progressive rise of temperature to 105.2 F and of the respiratory rate to 40 a minute. She died suddenly in her sleep thirty-two hours after admission. Postmortem examination was performed ten hours after death.

Autopsy—Externally the body revealed no gross abnormalities except for extreme rigor mortis and moderate abdominal distention. The organs of the abdomen were in normal position but the liver edge was about 3 cm below the costal margin. The stomach was greatly enlarged and through the visceral peritoneum the contents appeared definitely bluish. When the stomach was opened it was found to be filled with a tremendous clot of blood weighing 825 Gm. The mucosa of the stomach was well preserved and showed no abnormalities. The remainder of the gastrointestinal tract was considerably distended but section showed no pathologic changes and no evidence of a foreign body. The liver weighed 350 Gm and appeared in all respects normal. The gallbladder was normal in appearance. The spleen, pancreas, adrenals and kidneys manifested both grossly and on section no evidence of disease. The pelvic organs were normal. On examination of the thorax the right pleura was found to contain no free fluid. The right lung weighed 350 Gm. There were numerous fairly free adhesions at the inferior pole of the lower lobe to the dome of the diaphragm. The tissue was air containing throughout, cut with ease and showed slight congestion at the base of the lower lobe. The left pleural cavity contained 50 cc of yellow serous fluid. The left lung weighed 200 Gm. There were no pleural adhesions and the tissue was air containing throughout. The heart showed no abnormalities. The pericardial cavity, however, contained about 15 cc of yellow cloudy fluid. Examination of the esophagus revealed in the posterior wall, at the level of the fifth thoracic vertebra, a round ulceration 1 cm in diameter with thin margins. The lumen contained clotted blood. Posterior to the ulcerated area, in the areolar tissue between the esophagus and the aorta, there was a cavity 2 cm in diameter containing blood and lined with soft, friable brownish tissue. This cavity became narrow as it approached the wall of the descending aorta and was found to be continuous with an opening communicating with the lumen of that vessel. The perforation in the aorta measured 4 by 3 mm. The edges of the rent were ragged and thin. Microscopic sections of that portion of the esophagus which was perforated revealed edema and congestion of the tissue. Around the perforation there were dense collections of polymorphonuclear cells. Evidence of a foreign body was not found and it was assumed that the foreign body was washed into the esophagus by the force of the current of blood from the aortic perforation.

REVIEW OF THE LITERATURE

Ginsburg¹ in 1931 reported that a man aged 26 swallowed a small denture which lodged in the esophagus at the level of the fifth dorsal vertebra and eroded the aorta, causing death a week later by hemorrhage into the esophagus and stomach. In this case esophagoscopy was not done until the patient collapsed, when of course it was too late. Drejack² in 1934 mentioned among the other cases of his series that a man aged 49, without a history of having swallowed a foreign body, died five days after onset of symptoms. Autopsy revealed perforation of the upper part of the esophagus with erosion of the aorta by a splinter of bone. In this case the esophagus had also eroded into a principal bronchus. A fetid exudate was found in both pleural cavities. The esophageal defect was the size of a lentil.

Tucker³ reported in 1932 that an infant aged 7 months who had previously been well suddenly became paler than usual,

seemed to have difficulty in swallowing, developed fever and later vomited blood. X-ray examination revealed an open safety pin in the esophagus. After the patient had been removed to a hospital it was found that the pin had passed into the stomach. Later it was passed rectally, but the child died of exsanguination from a small perforation of the aorta via the esophagus. Autopsy further revealed an acute purulent pericarditis and minute embolic abscesses of the kidneys. The author emphasizes the importance of early x-ray examination of every child who experiences the slightest difficulty in swallowing.

Turner⁴ in 1910 reported that a boy aged 6 years died of perforation of the aorta by a coin which he had swallowed twenty-two months before. This patient had had initial symptoms of a foreign body in the esophagus but these had disappeared and he was symptom free until he began to vomit blood three days before his death. At autopsy the coin was found impacted transversely at the level of the left bronchus. Turner reported 4 other cases of erosion or perforation of the aorta, 2 from rabbit bones and 2 from fish bones.

Lovett⁵ in 1909 reported that a boy aged 8 years began suddenly to vomit blood and to pass tarry stools. He died of exsanguination in a few days. He had swallowed a half penny coin at the age of 4 but had not had an x-ray examination. He was treated conservatively, and when he became symptom free the matter was forgotten until the terminal illness. The coin was recovered from the upper part of the esophagus at the post mortem examination. It had slowly eroded into the aorta, death occurring from hemorrhage through a hole the size of a pinhead.

The literature contains many reports of the perforation of vessels other than the aorta by foreign bodies in the esophagus. A typical one is that of Sneller,⁶ who in 1936 reported a case of profuse arterial bleeding following perforation of the esophagus by a chicken bone. Ter-Oganesjan⁷ reported 50 such perforations of great vessels and Killian⁸ 12 more.

Swan⁹ in 1930 reported a traumatic aortic-esophageal fistula in a 10 month old baby who swallowed a small piece of nickel plated wire. Decoulx and Omez¹⁰ in 1939 reported that a man aged 41, a miner, suffered dysphagia after he swallowed a chicken bone and subsequently bled to death from an aortic esophageal fistula following a crushing chest injury in the mine. The conclusion was that the esophageal ulceration from the bone predisposed to the final rupture and that the thoracic trauma precipitated it. The chicken bone was not found.

COMMENT

Death from mediastinitis, empyema, pyopericardium and erosion of great vessels has been reported from time to time in case reports dealing with foreign bodies in the esophagus. In cases in which there is erosion of vessels the great vessels of the neck are more commonly perforated, the great thoracic vessels and the heart less commonly. Perforation of the thoracic aorta by a foreign body in the esophagus, while not rare, is sufficiently uncommon to warrant being reported.

CONCLUSION

All patients suspected of having a foreign body lodged in the esophagus should be studied early by roentgenography and esophagoscopy. If symptoms persist despite negative x-ray findings, diagnostic esophagoscopy is demanded. Esophagoscopy itself is rarely responsible for a fatality and will often be life saving if undertaken early. Only by accurate history taking and prompt action in suspected cases is it possible to prevent a fatal issue in the type of case reported here.

XANTHOMA OF TENDON SHEATH

DAVID S. CRISTOL, M.D., ROCHESTER, MINN.
AND A. BRUCE GILL, M.D.
PHILADELPHIA

While xanthomas of tendon sheaths or of synovial membranes are not too rare, they are worthy of consideration because frequently they are known to perplex the unsuspecting physician. The following case illustrates the difficulties in the diagnosis and treatment of this condition. It is presented because, while it illustrates most of the essential features of this condition, it is one of the most extensive lesions yet recorded.

REPORT OF CASE

H. W., a white man aged 46, married, was first admitted to Dr. Gill's orthopedic service in the Hospital of the University of Pennsylvania on March 26, 1924, complaining of pain and swelling of the left foot. He stated that the pain started approximately three years before without any definitely known cause save the possibility of repeated minor injuries received while bowling. Pain was very slight at first and some swelling of the left foot and lower ankle was appreciated after six months. He consulted a physician, who prescribed arch supports after receiving a negative x-ray report. He got along fairly well with these but did experience ever increasing discomfort for the six months prior to admission to the hospital. The pain was never severe enough to prevent him from walking. On admission a moderate amount of swelling was present behind and below the medial malleolus and the inner side of the tarsus of the left foot extending along the course of the tendon of the tibialis posterior muscle. On March 27, 1924, under ether anesthesia, five small tissue masses were removed from his left foot and they were diagnosed as 'mixed cell sarcoma of alveolar arrangement with much degeneration and blood pigment.' He returned on April 9, 1924, when another piece of tissue was removed. This was diagnosed as being 'xanthomatous' and the patient was referred for x-ray therapy. An x-ray examination on Nov. 6, 1924, revealed no evidence of recurrence. He returned again on Feb. 19, 1925, at which time the following was recorded: 'There is a soft doughy mass present in the region of the inner surface of the left foot in the same area as was occupied by tumor. This is suggestive of an extension or a recurrence of the original tumor. Recommend further x-ray treatment. Has had no x-ray treatment since October 1924.' On June 26, 1928, examinations revealed no evidence of recurrence and the patient was discharged from the x-ray department. He returned on May 7, 1942, at which time a soft tumor measuring 2 by 3 inches over and below the left medial malleolus and definite soft tissue thickening of the entire foot on both the dorsal and the plantar aspect were observed. The skin appeared thin over the tumor but appeared normal about the foot. Pain and tenderness were absent and weight bearing was painless. Dr. Gill saw the patient and advised amputation because, while the lesion was probably not malignant there was the possibility of its becoming so. The patient stated that he first noticed the presence of this swelling or tumor, about three years previously in the region below the internal malleolus and that it had gradually grown in size and extended into the entire foot, but that during the past year the growth had been more rapid.

The history by systems was essentially negative with no history of weight loss. The family and social histories were noncontributory. Physical examination revealed that the temperature was 98 F, the pulse rate 70 and respiratory rate 20. The blood pressure was 156/72 mm. of mercury in both arms while recumbent. The patient was somewhat obese and though 63 years of age appeared to be about 50. He was ambulatory and in no distress. A small tender nonfixed nodule was observed over the left eyebrow measuring 1 by 5 cm. A soft apical blowing systolic cardiac murmur was heard. The left foot appeared as described. Laboratory examination

revealed hemoglobin 88 per cent, white blood cells 5100 with a normal differential, negative blood Wassermann reaction, normal blood calcium, phosphorus and phosphatase and normal urine. X-ray examination of the left leg and foot on May 12, 1942, revealed erosive bone changes in the left ankle and foot suggesting extensive pressure. On May 14, using ether anesthesia, Dr. Gill incised the mass on the medial aspect of the left foot and found that it contained yellowish necrotic material. This extended throughout all the enlarged parts of the foot. It was fairly vascular. A specimen was sent to the laboratory. Removal of the tumor tissue was impossible, as it extended into all the soft structures of the foot. Amputation was done at the junction of the middle and upper thirds of the leg. No difficulties were encountered. The patient was returned to the ward in good condition and was given parenteral fluids. The amputated left foot (upper tibial amputation) was increased in size with tissue tense and bulging, especially around the inner aspect. Subcutaneous tissues down to the bone were filled with bundles and lobules of orange yellow soft tissue. The tissue was stained with dark blood in many

Fig. 1.—Section of foot illustrating most likely origin of tumor. Section made by band saw after two hours fixation with solidified carbon dioxide. Specimen allowed to thaw out in Klotz solution number 1.

areas. Process completely surrounded the thinned metatarsals without invasion. Microscopic examination revealed foam cells (xanthoma cells) containing intracellular fat and cholesterol crystals, cholesterol clefts, foreign body giant cells, typical endothelium-like stroma cells and interlacing strands of fibrous tissue. The diagnosis was xanthoma of the tendon sheath.

Microscopic study prompted estimation of the patient's blood cholesterol which was found to be 276 mg. per hundred cubic centimeters with esters 181 mg. per hundred cubic centimeters. The patient's postoperative course was entirely uneventful and he was discharged two weeks later.

COMMENT

A clinical and pathologic study of this problem was published by Galloway, Broders and Ghormley¹ in 1940. They reviewed the literature and added 70 cases. Their investigations showed that these are slowly growing painless tumors averaging approximately five years to develop before they are discovered. While the tumor varies in size and shape, it is a

Dr. Cristol, formerly a member of the Department of Pathology of the University of Pennsylvania Medical School and Hospital, is now urologic fellow at the Mayo Clinic. Dr. Gill is professor of orthopedics of the University of Pennsylvania Medical School and Hospital.

1. Galloway, J. D. B., Broders, A. C. and Ghormley, R. C. Xanthoma of Tendon Sheaths and Synovial Membranes. A Clinical and Pathologic Study. *Arch. Surg.* 10: 555-558 (Mar. 5) 1940.

ages 25 to 30 by 20 cm when first seen by the physician and in most cases is a firm, round or oval lesion. Galloway and his collaborators found that these lesions occurred most commonly on the fingers, and on the upper extremity two to three times as often as on the lower extremity. They found that the largest number of cases fell in the third to sixth decades,

and that the secondary factor is trauma or infection at the site of the lesion."

Most authors regard these lesions as benign and many also point out their potential malignant nature, especially in those occurring in the palm of the hand, forearm or foot. Many authors believe that these tumors are of inflammatory origin. Some authors believe them to be inflammatory with a secondary disturbance in lipid metabolism, while others believe that they are only associated with a cholesterol diathesis and result from the removal of the excess cholesterol from the blood. Galloway and his collaborators believe that these tumors should be classified as one of the primary essential xanthomatoses and agree with the classification of Thannhauser and Magendanz.

In the diagnosis we could describe a typical case as occurring in either sex around 40 years of age with a firm, round or oval subcutaneous mass measuring approximately 2 to 3 by 2 cm, painlessly growing in size and located on or associated with a tendon sheath, most typically the flexor of a finger. The most characteristic case will present a history of previous trauma and the blood lipoids will demonstrate an absolute increase or an alteration in the ratio of cholesterol to cholesterol esters. The x-ray examination will prove normal. In joint involvement there may or may not be heat and pain, and examination of the aspirated joint fluid will reveal a high cholesterol content. These tumors are harder than lipomas and softer than chondromas. Unlike carcinoma, they do not involve the skin. Osteomas are harder and are connected with the bone, while ganglions are usually on the extensor surface, besides being much softer. Biopsy and surgical removal will always reveal the true diagnosis. Local excision, even if repeated with recurrence, is the choice method of treatment.

Fig 2—Microscopic section of tumor demonstrating cholesterol clefts above separated by fibrous septums from foam cells below, $\times 200$

the average age in their cases being 44 years. The two sexes were found to be about evenly involved with a very slight female preponderance. It was felt that principally trauma of a mild, constant and unnoticeable type, and possibly infection were important secondary factors in the production of these tumors. They concluded that the alteration in lipid metabolism was the primary etiologic factor, with trauma and infection or both being a secondary factor. In a review of the pathologic picture it was believed that the foam cell originated from the reticuloendothelial system and its contained cholesterol was present via infiltration. It was also believed that the giant cells, which along with the foam cells are characteristic elements of this tumor, were morphologically identical with osteoclasts and differed from them only in their affinity for different foreign materials. The contained pigment is believed by some to result from the breaking up of the red blood corpuscles of the extravasated blood in the tissues or, as Wells believes, from the presence of either carotene or xanthophyll pigments or both, which are normally present in the blood serum and are readily taken up and combined with cholesterol fatty acid esters. These mentioned elements, together with the type cell, complete the diagnostic pathologic picture. The type or stroma cell is morphologically similar to the endothelial cell and its fat content is made up chiefly of cholesterol or of its esters, being intracellularly arranged in most cases.

Concerning the pathogenesis, the authors mentioned believe that "the primary factor in production of this tumor is a pre-existing alteration in the lipid metabolism in which there is either a marked disturbance in the absolute values of the blood lipoids, or even more important, a disturbance in the ratios of the various constituents, chiefly that of cholesterol to esters,

Fig 3—Microscopic section of tumor showing pigment content of foam cells, with some typical endothelium like cells of the stroma, $\times 400$

The value of x-ray therapy is still to be more critically evaluated, but some authors have reported good results. Low cholesterol diets are prescribed for patients who show high blood values.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORT HOWARD A. CARTER, Secretary

HANOVIA SAFE-T-AIRE FILTER JACKET TYPE QUARTZ LAMPS (Hospital Operating Room, Nursery and Ward Models) ACCEPTABLE

Manufacturer Hanovia Chemical & Mfg Co Newark, N J
Clinical evidence submitted to the Council on Physical Therapy shows that under properly controlled conditions ultraviolet radiation is effective in killing air borne micro organisms and may be used to supplement other measures for the prevention of cross infection in hospital wards and nurseries and in operating rooms for reduction of air borne infections in wounds. On the basis of this evidence the Council has undertaken the consideration of ultraviolet disinfecting lamps designed for installation in operating rooms hospital nurseries and hospital wards. Council acceptance is limited to these installations only because the available data do not substantiate the claims for disinfecting of air by ultraviolet radiation in schools, waiting rooms public gathering places and homes or for the sterilization of solids such as drinking cups. Ultraviolet radiation cannot penetrate deeply and may be absorbed by finger marks saliva cosmetics or other foreign matter on a drinking cup this would render the radiation ineffective. To kill a micro-organism a direct hit by ultraviolet rays of sufficient intensity is required.

To have effective disinfection of air by ultraviolet radiation it is necessary for a sufficient number of properly placed lamps to be installed. A lamp used for disinfecting purposes is a single unit in an installation compliance of the ultraviolet output of a single lamp unit with the Council's requirements does not insure adequate radiant disinfection. Adequate ventilation is a necessity because dust laden air provides protection for air borne micro-organisms against the ultraviolet radiation.

In an installation of ultraviolet disinfecting units the total amount of direct and scattered ultraviolet radiation incident on the occupants must be kept below the level that will produce conjunctivitis erythema and any other (at present unforeseen) injurious physiologic effects that may arise from prolonged irradiation. This requirement should be met by suitable arrangements of the lamp fixtures and baffles and not by requiring the personnel to wear glasses and special covering of exposed parts of the body (face hands) normally uncovered. Hence if the irradiation is of penetrating intensity in a corridor or the hospital for example, care should be taken that the attendants do not receive an exposure which will cause injury to the skin or eyes and particular attention should be taken to make sure that the intensity of the space at eye level through which a transient may pass or tarry momentarily will not cause injury to the eyes. Under no circumstances should the occupants of a room be able to look directly at the burner when standing within the region of potent intensity.

Ultraviolet lamps for disinfecting purposes shall have under suitable ventilating conditions of a room a concentration of ozone not to exceed one part in ten million.

The Hanovia Safe-T-Aire Quartz Lamps Filter Jacket Type generate ultraviolet radiation of wavelengths between 2500 and 2600 angstroms and are said in the firm's literature to 'turnish air sanitation and by this means to lessen the danger of infection through air borne organisms'. The lamps are available in ceiling suspension models wall type equipment operating room models and floor stand models and the Baryaire Safe-T-Aire equipment.

Evidence consisting of reports from several investigators having used in their experiments the Safe-T-Aire burners and other lamps said to have disinfecting properties was presented by the firm. That ultraviolet radiation from the Safe-T-Aire will destroy bacteria within a specified distance and under required conditions is substantiated in the evidence submitted.

The ceiling suspension lamp comprises an indirect lighting fixture suspended by three chains to a height of about 6 to 7

feet from the floor at its lowest point. The burner housing is bowl shaped and of polished aluminum and is about 20 1/2 inches in diameter. A polished reflector is mounted in the housing.

Wall type Safe-T-Aire equipment is designed to be mounted on the side wall of a room at a point where the radiations will cover the largest area.

The operating room model is arranged for ceiling or wall mounting. It is usually fixed on the wall at ceiling height or at a distance usually not greater than 14 feet from the floor.

The floor stand unit is said to be "designed to fill the need for a portable unit which can be moved at will. The general design of the lamp is similar to an indirect illuminating lamp." The upright finished in polished chromium supports the burner above eye level.

The Baryaire Safe-T-Aire equipment is usually installed in pairs at opposite points across the width of a hospital corridor to help prevent the passage of air borne micro-organisms. Approximately 24 inches square and 9 inches deep, the unit is equipped with a fan which draws air past the upper and lower burners.

The Safe-T-Aire burner which is incorporated in each of the fixtures mentioned is tubular standard sizes are 12 and 24

Technical Information for Quartz Safe-T-Aire Lamp Filter Jacket Types

Specification	Catalogue No. 2831 J Filter	Catalogue No. 2832 J Filter
Effective burner length	12 inches	24 inches
Overall burner length	16 3/8 inches	29 1/4 inches
Operating control		
Supply input voltage	110/120 volts	110/120 volts
Supply frequency	60 cycles AC	60 cycles AC
Lamp circuit		
No load voltage	3 000 volts	3 000 volts
Burner operating voltage	450 volts	600 volts
Burner watts	7	10
Burner current	30 milliamperes	30 milliamperes
Supply input current	1.25 amperes	1.20 amperes
Power factor	0.19	0.21
Supply watts	26 (at 115 V)	29 (at 115 V)
Lamp radiation characteristics		
% ultraviolet at 2 537 angstroms	96%	96%
Intensity of 2 537 angstroms for new lamp with clean reflector or Alzak aluminum distance 1 meter (line voltage 115 volts)	22 mw/cm ²	48 mw/cm ²
Effective burner life	over 10 000 hrs	over 10 000 hrs
Percentage loss in effectiveness with usage		
After the first 1 000 hours		5% loss
After the next 2 000 hours		7% additional
After the next 3 000 hours		3% additional
After the next 5 000 hours		2% additional
Total loss in effectiveness in 1 000 hours		19%

inches long. The envelop of the burner is of pure transparent fused quartz. Cathode connections are sealed in the quartz tube without the use of intermediate glass. The tube operates from alternating current through the medium or a high voltage transformer with a primary supply voltage of 110 or 220 volts. A filter jacket is provided to limit the production of ozone.

Users of the lamps are advised to have the intensity checked at periodic intervals by company representatives or other qualified persons. After ten thousand hours of use the intensity or effectiveness of the Hanovia burner falls off more rapidly and it should be replaced after it has been used ten thousand to fifteen thousand hours.

These lamps are a very intense source of 2537 angstroms ultraviolet radiation. The eyes must be carefully protected from direct radiation from the lamp.

When a unit is installed the purchaser should make sure that a sufficient number of lamps are used to produce the correct amount of intensity in the enclosure and that they are arranged correctly so as not to cause harm to the occupants. The Council cannot undertake the supervision or assume the responsibility for satisfactory performance or any particular installation.

The Council voted to accept the Hanovia Safe-T-Aire Filter Jacket Type Quartz Lamp Operating Room Ward and Nursery Models for inclusion on its list of accepted devices. Models which are unequipped with the filter jackets to prevent the production of ozone are not acceptable for disinfection purposes.

MORE DOCTORS NEEDED FOR THE ARMED FORCES

At a conference of the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, held on July 31 with the War Participation Committee of the American Medical Association and in the presence of Mr Paul V McNutt, chairman of the War Manpower Commission, and representatives of the Army and Navy medical departments and the Public Health Service, it became apparent that the medical profession must produce toward the winning of the war an additional six thousand physicians for the armed forces before Jan 1, 1944. Pursuant to a realization of this objective a directive has gone to the generals in command of the various service commands authorizing them to induct into the service physicians between the ages of 38 and 45 who have been declared available by the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians and who are otherwise subject to Selective Service.

The needs of the armed forces are real. The members of the War Participation Committee raised with the representatives of the various governmental agencies all the questions that have from time to time challenged the need, the challenge seems to have been met effectively. Indeed, the intimation was made clear that the needs of the armed forces will be met

by specific regulations of the Selective Service Administration or the enactment of necessary legislation if required. All physicians up to 45 years of age who have been indicated as available have therefore placed on them now the responsibility for an immediate decision as to their enlistment with the armed forces. The need is so positive that questions of essentiality of men in positions of teaching and research and in industrial medicine are likely to be rigidly reviewed in the near future with a view to extracting from civilian life every one that can be spared.

As the war continues and intensifies, new needs for the services of the medical profession become apparent. An army in motion and one engaged in the kind of aggressive combat that now concerns our armed forces needs physicians in even greater numbers than have heretofore been demanded. Many thousands of interned aliens and prisoners are now the burden of the United States and must be given medical care.

If there is any physician who still hesitates under these circumstances, he should realize the added advantage to him of accepting now the commission that is proffered. Should it become necessary in the near future, as seems quite likely, to enlist new activity by the Selective Service Administration and the Officers' Procurement Service to bring in the six thousand

physicians that are so certainly required, those recruited by that technic will inevitably begin their service with the minimum commission that is offered, namely that of first lieutenant. Until that technic is installed, the men of special competence and of years beyond those of the recent graduate have the assurance of careful consideration and a commission more nearly in accord with age and experience.

The call here made has the approval of the Directing Board of the Procurement and Assignment Service and of the War Participation Committee of the Amer-

ican Medical Association. The medical profession may well be proud of the fact that it has been the only group given, by directive of the President, the responsibility of maintaining service in civilian life and at the same time supplying the needs of the armed forces. Let us not fail in meeting fully the trust that has been placed upon us.

HYPERADHESIVE THROMBOCYTES

A rise in blood platelet count following childbirth or surgical operation is a well established clinical phenomenon and is believed to be a contributory factor in postoperative or postpartum venous thrombosis. This rise begins about the fourth day after operation or delivery and attains its maximum about the tenth day, the number of circulating platelets subsequently falling to the normal by the twenty-first day. The period of hyperthrombocytemia corresponds roughly with the period in which venous thrombosis generally occurs. The correspondence, however, is not complete. To account for this divergence, MacKay¹ postulated a second thrombogenic factor, an increased agglutinability or adhesiveness of blood platelets.

A technical method of measuring relative platelet "stickiness," therefore, was developed by Wright² of Guy's Hospital, London. After addition of an anticoagulant, blood samples are revolved slowly in glass tubes the rate of decrease in the platelet count being taken as a measure of the number of thrombocytes that became adherent to the glass surface. In normal blood samples about 33 per cent of the initial platelets became adherent after twenty minutes' rotation, increasing to 67 per cent by the end of eighty minutes.

This technic has now been applied to a series of obstetric and surgical cases.³ By the fourth day after operation or delivery a distinct increase of adhesiveness was noted, increasing to a maximum "stickiness" by the tenth day. At this time an average of nearly 90 per cent of the platelets became adherent to the glass surface in their routine test. After the tenth day the stickiness gradually decreased, the platelets being restored to normal by the twenty-first day. In paraffined control tubes practically no platelets become adherent.

Plotted as a curve, this increased "stickiness" shows a closer parallelism with the percentage incidence of thrombophlebitis⁴ than that shown by the increased platelet count. Wright concluded from this that the presence of "exceptionally sticky platelets" is the essential etiologic factor in postoperative and postpartum thrombosis.

Parallel studies of sedimentation rates indicated that this increased adhesiveness is not due to plasma changes but must be attributed to alterations in the platelets themselves. Wright therefore postulates that new formed blood platelets are hyperadhesive and that there is a progressive reduction in their initial stickiness as the platelets age. Whether or not excessive formation of these hyperadhesive platelets can be prevented by blood transfusion or other therapeutic measures has not yet been determined.

Current Comment

BOSTON MEDICAL POLICE

In 1808 the Boston Medical Association adopted a code of Medical Police¹ which its standing committee had been instructed to prepare. This code was based on the ethical teachings of Gregory, Rush and Percival, with changes and additional matter to meet better the conditions in Boston at that time. The subjects covered are consultations, interferences, differences of physicians, discouragement of quackery, conduct for the support of the medical character, fees, exemption from charges, vicarious offices and seniority. Physicians in consultation "should divest themselves of all partialities and think of nothing but what will most effectively contribute to the relief of those under their care." By "interferences" is meant meddling inquiries and hints or other selfish conduct of any kind by physicians that might tend to weaken the confidence of the patient in his physician. The practice of medicine should be founded on qualification, not on artifice and insinuation. The section on quackery follows:

"The use of quack medicines should be discouraged by the faculty, as disgraceful to the profession injurious to health, and often destructive even of life. No physician or surgeon, therefore, should dispense a secret nostrum, whether it be his invention or exclusive property, for if it is of real efficacy, the concealment of it is inconsistent with beneficence and professional liberality, and, if mystery alone give it value and importance, such craft implies either disgraceful ignorance, or fraudulent avarice."

Under fees we read that "the poor of every description should be the objects of our special care." Clergymen and all members of the medical profession together with their families should be attended gratuitously. In June 1830 revised rules and regulations were adopted by the association and printed, together with the Medical Police and a list of members.¹ The rules provided for the conduct of the business of the association as well as of medical practice. A detailed table of "regular fees" is included. Here are samples. The common fee for a visit, \$1.50, for advice at the physician's house according to the importance of the case and the time occupied, \$1 to \$10, for a postmortem examination in a case of legal investigation, \$5, for vaccine inoculation \$5, for capital operations, such as amputations of large limbs, lithotomy, trepanning and extirpation of large tumors \$40. With certain exceptions the fees listed were the lowest the members should demand. Members were not allowed to contract to give annual service to any family for a definite sum. According to paragraph VI no member should "consult with or voluntarily meet in a professional way or aid or abet any practitioner resident in this town who is not a member of the association." One wonders how this rule worked out in practice. Full provision was made for the admission of new members on the basis of approval of these regulations. From its foundation in 1806 to July 1830 the association had 170 members. This

glimpse at medical organization in the beginning of the last century reveals the high ideals that governed Boston physicians of that day in their strivings to maintain and advance the ethics of the practice of medicine

SYNTHESIS OF BIOTIN

Biotin, a factor in the B complex, is of unusual interest. It is involved in animal metabolism and also is capable of exerting a noticeable biologic effect, under appropriate test conditions, in a dilution of one to four hundred billion,¹ thus ranking as one of the most active substances known. A comment on the determination of the structure of this potent compound by du Vigneaud and his collaborators was published some months ago in THE JOURNAL. At that time it was pointed out that the elucidation of the chemical makeup of the vitamin was an initial step in the direction of making it more readily available through synthesis. This synthesis was not long in forthcoming, for the preparation of synthetic biotin has now been reported.² The material possesses a complex chemical structure and includes in its makeup three different asymmetrical carbon atoms. The latter fact makes possible the existence of several stereochemical isomers related to biotin. Synthesis of a product possessing not only the structure but also the stereochemical configuration of natural biotin was an accomplishment of the first magnitude. A comparison of the physical and chemical properties of the synthetic product with those of naturally occurring material revealed no difference between the two substances. The crucial test was a comparison of the biologic activity of the two chemical compounds as determined by experiments with biotin deficient chicks and rats. The physiologic response of biotin deficient animals to the synthetic product was the same as to the naturally occurring biotin. The way has thus been cleared for the production of amounts of biotin which will greatly facilitate the carrying out of experiments designed to increase our knowledge of this member of the vitamin B complex. Kogl and Tonnies,³ who isolated biotin for the first time, were able to obtain only 1 mg of the crystalline material from a quarter of a ton of dried egg yolk.

DOMESTIC CARBON MONOXIDE POISONING

A report¹ has been published on the results of a cooperative study of the effects of carbon monoxide on the health of persons more or less habitually exposed to smaller and larger quantities of the gas in the air they breathe. This study was carried out by a committee under the joint auspices of the University, the State Board of Health and the Geological Survey of West Virginia in conjunction with a number of gas companies. In this study special attention was

given to the effects of carbon monoxide on health under domestic conditions. The engineering survey revealed that in many homes one or more gas appliances discharged carbon monoxide into the rooms, some of them in large quantities. The clinical studies in general confirmed the description by Henderson² of the effect of repeated exposures to small amounts of carbon monoxide "such as a mechanic in an automobile repair shop breathes day after day, or a workman at a blast furnace or gas plant, or a cook working in a small badly ventilated kitchen with a defective gas stove. The results of such conditions are impairment of general health, nervousness, ill temper" and other general symptoms. The West Virginia investigators report that the symptoms will vary in intensity, depending on the quantity of monoxide in the air breathed, the length of exposure, the amount of monoxide in the blood, the activity and previous condition of the patient and other factors. In a field survey of the health and living conditions of 279 persons who lived at home or worked in shops in which natural gas was consumed for cooking or heating, 137 gave histories suggestive of carbon monoxide anoxemia, mostly of a simple and uncomplicated form. The diagnosis in these cases was based mainly on definite exposure to the monoxide gas, on subsidence of symptoms when the exposure ceased, on the presence of monoxide in the blood whenever it was possible to make the necessary tests, and on exclusion of other diseases. It is to be noted that these milder forms of monoxide poisoning do not present any distinctive clinical picture, the manifestations being essentially subjective. In suspected cases the definitive diagnosis will require proper chemical examinations of the blood of the patient as well as of the air he has been breathing.

STABILITY OF VITAMINS AND WHISKY

Present government regulations make it illegal to add vitamins to alcoholic beverages. Nevertheless, the fact that many of the diseases associated with chronic alcoholism are due primarily to deficiencies in the vitamin intake of the excessive drinker make information on the stability of vitamins in whisky of more than academic interest. Novak and Adams¹ investigated this question by fortifying a standard brand of 86.8-proof whisky with riboflavin, thiamine and nicotinic acid. Part of the whisky was exposed to daylight in clear bottles and part in amber bottles, and a control portion was stored in the dark. The result of the assays showed that riboflavin is unstable in whisky, since a reduction of 50 per cent of the amount added occurred in both paper-wrapped and amber bottles at the end of the two month period. At the end of six months assays indicated that loss of thiamine or nicotinic acid had not occurred and that these members of the vitamin B complex appear to be stable in whisky. Even if it should become legal to add vitamins to alcoholic beverages, physiologic considerations would incline to make such formulas undesirable.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

LIEUT COL LEON S EAGLEBERGER TO INSTRUCT PHYSICIANS IN COMBAT MEDICINE

Lieut Col Leon S Eagleberger of the Army Medical Corps with a great wealth of experience concerning medical support of United States troops battling the Japanese in the Southwest Pacific has returned to the United States to instruct newly commissioned officers in combat medicine at the Medical Field Service School Carlisle Barracks Pennsylvania. Colonel Eagleberger states that the portable hospitals in which doctors performed surgery in the jungle only a few hundred yards behind the front lines were the 100 per cent solution to the problem of giving adequate surgical service in that area. Blood plasma which was available in sufficient quantities was used unsparingly thereby saving many lives. The portable hospitals consisted of four medical officers and twenty enlisted men with one such hospital for each regiment. Every general hospital station hospital evacuation hospital and surgical hospital in Australia had been ordered to organize one such unit.

Colonel Eagleberger whose home town is Waupun Wis graduated from Rush Medical College in 1930. He was called into federal army service in January 1941 and spent eight months in New Guinea from the start of the United Nations operations there until April of this year. He commanded a battalion of a medical regiment. In May 1942 he was ordered to take part of his battalion to Port Moresby to establish a provisional hospital and to pave the way for the larger hospitals which would later move into that area.

LIEUTENANT COLONEL BUNSHAW CITED

Lieut Col Raymond H Bunshaw A U S whose home is in Erie Pa has been cited for especially meritorious conduct in the performance of his duties on Guadalcanal, where he is still serving. According to the Erie Pa Times the citation reads as follows:

for exceptionally meritorious conduct in the performance of services of a considerable degree of merit on Guadalcanal Solomon Islands from Jan 10 to Feb 9 1943. As commanding officer of a medical battalion in an infantry division of which he was also division surgeon. Lieutenant Colonel Bunshaw succeeded in arranging the evacuation of casualties of the division in spite of the handicaps of extremely difficult terrain lack of roads and the isolated positions of many units.

This he accomplished by displaying outstanding initiative energy and by developing many improvisations and innovations in procedure to overcome the local conditions. His professional knowledge was employed and proved in the successful execution of the difficult task of the hospitalization by his battalion of twice the number of patients it was equipped to care for.

SELECTION OF PREMEDICAL STUDENTS

In compliance with recent army regulations Indiana University School of Medicine has announced the selection of 154 premedical students for entrance to the school in May 1944. The selections were made by a committee of fourteen faculty members and practicing physicians with Dr C H McCaskey of Indianapolis as chairman and are subject to maintenance by the students of satisfactory grades and conduct. On account

of this provision the total of 154 selected is 16 per cent above the quota of the school. The premedical students selected are enrolled for premedical study in Indiana University and twenty-three other colleges and universities among the selectees are nine women.

GRADUATE MEDICAL ADMINISTRATIVE OFFICERS

The nineteenth class of the Camp Berkeley Medical Administrative Corps Officer Candidate School graduated on July 7 following a special course of twelve weeks which now has been lengthened to sixteen weeks. These former noncommissioned officers studied problems of supply personnel training and evacuation and as officers in the medical administrative corps will take over such duties in hospitals camps and elsewhere, thus relieving medical officers to apply their professional skill to the treatment of the sick and wounded. The graduation address was delivered by Hon Jesse E Martin state senator from Fort Worth who was introduced by the school commandant Brig Gen Roy C Hefebower.

NINTH CLASS OF AVIATION PHYSIOLOGISTS

Graduation exercises at the School of Aviation Medicine Randolph Field Texas for the ninth class of Aviation Physiologists was held on July 10. The course in aviation physiology is of five weeks duration. Among those graduating were the following officers of the medical corps:

Capt Fred Dumstra Sioux Falls S D
Capt Herbert D Krieger Beverly Hills Calif
Capt John R Orndorff River Forest Ill
1st Lieut Seaburt Goodman Cleveland
1st Lieut Harold L Graber Topeka Kan
1st Lieut George A Hallenbeck Rochester Minn
1st Lieut Vincent J Palmeri Newark N J
1st Lieut Bradford D Rodgers Deming N M
1st Lieut Sidney I Smith Sheridan Ill
1st Lieut Oliver H Straus Boston
1st Lieut Orville O Witherbee Santa Ana Calif

THE TORNEY GENERAL HOSPITAL

The Torney General Hospital has been established at the El Mirador Hotel in Palm Springs Calif following the purchase of that hotel by the government. By August of 1942 there were facilities for 500 patients and it is planned that on completion there will be 1600 patient beds available. The hospital was named after Brig Gen George Henry Torney Surgeon General of the Army from 1909 to 1913 during whose term of office inoculation against typhoid was started in the army.

The commanding officer at Torney General Hospital is Col Augustus B Jones a distinguished internist. Major Edward F Thompson of Milwaukee is executive officer. Col Maurice A Schinger is chief of the medical service from Washington D C. Lieut Col William C Sheehan chief of the surgical service from Philadelphia. Major Hans F Strutana chief of the laboratory service from New York. Major Willard L Nielsen chief of the dental service. Major William A Kunkel from Memphis Tenn chief of the x-ray service and Major Julian N Dow chief of the evacuation and treatment service, formerly of Los Angeles.

NAVY

ARMY-NAVY HOSPITALIZATION

According to the Bureau of Medicine and Surgery, in an agreement reached between the Army and Navy, all charges for the care of personnel in each other's medical facilities will be discontinued. Heretofore when army personnel were treated in naval facilities the War Department was billed, which was reversed when navy personnel received treatment in Army facilities. In the future, members of the armed forces may be treated in Army and Navy facilities without reciprocal billing.

LIEUT THIRL E JARRETT AWARDED
SILVER STAR MEDAL

Lieut Thirl E Jarrett, MC, USN, has been awarded the Silver Star Medal for conspicuous gallantry and intrepidity while serving as a medical officer at the Division Field Hospital during action against enemy Japanese forces on Guadalcanal in October 1942. On repeated occasions, while the hospital was under tremendous bombardment by hostile warships, Lieutenant Jarrett, with utter disregard for his own personal safety, worked tirelessly over his wounded comrades, administering plasma, rendering first aid and performing invaluable medical service under difficult and dangerous conditions. By his calm professional skill and loyal devotion, maintained above and beyond the call of duty, he undoubtedly saved the lives of many men who otherwise might have perished. Lieutenant Jarrett graduated from the University of Oklahoma School of Medicine in 1936 and after his internship and residency was commissioned as a lieutenant (jg), MC-V(G), USNR, on

May 1, 1941, was commissioned a lieutenant (jg) (MC), USN, on Oct 20, 1941 and commissioned a lieutenant (MC), USN, on June 15, 1942. His home address is Brooklyn.

AWARDED LEGION OF MERIT

Comdr Don S Knowlton, MC-V (S), USNR, has been awarded the Legion of Merit for his brilliant leadership, which made possible evacuation and hospitalization of Guadalcanal wounded despite heavy Japanese air and surface craft fire. The citation reads as follows:

"For exceptionally meritorious conduct in the performance of the outstanding services to the government of the United States as executive officer of the First Medical Battalion during the seizure and occupation of Guadalcanal, Solomon Islands.

"Under extremely difficult and dangerous conditions, Commander Knowlton, by his untiring effort and skilful organizing ability, developed a high state of efficiency in the medical battalion, particularly at the division field hospital.

"The steadfast functioning of this unit as a principal evacuation and medical supply center of the division, in an area heavily bombarded by Japanese air and surface craft, is attributable to his brilliant leadership and excellent training of subordinate personnel."

Commander Knowlton graduated from Tufts College Medical School, Boston, in 1921. He entered military service, Nov 5, 1940, and is now camp medical officer and commanding officer of the Medical Field Service School, Infantry Battalion, Camp Lejeune, New River, N C.

CIVILIAN DEFENSE

ORGANIZATION PLAN FOR RESCUE
SERVICE

Plans for the organization of the Rescue Service, which is responsible for the recovery of persons trapped under the structural debris of demolished buildings in the event of enemy action, were issued on June 24 by James M Landis, director of the U S Office of Civilian Defense, in Operations Letter No 133.

To guide the development of a trained Rescue Service in the United States Citizens Defense Corps, an engineer officer of the U S Public Health Service, Mr Simon H Ash, has been designated chief of the rescue section of the Medical Division of the OCD. Mr Ash has recently returned from a month's visit to Britain, where he studied the British rescue organization and training methods.

Although the Rescue Service is being organized nationally under the direction of the Medical Division of OCD, state and local rescue services will be separate from the Emergency Medical Service. Local chiefs of rescue and emergency medical services will work in close coordination in the control center. When reports are received of persons trapped by the debris of buildings demolished by an air raid or other enemy action, an express party is dispatched, which consists of one rescue squad, one mobile medical team and one ambulance and one sitting-case car.

Rescue workers, who should be recruited from workers in the building and demolition trades, mine workers, mechanics, petroleum industry workers and tunnel workers in the heavy construction industry, are to be organized in squads of ten. The squads should be based in depots, each of which should have a complement of three squads rotating on periods of first call. The OCD recommends an average of one depot for each 50,000 population in target areas. The national program contemplates an establishment of about 1,000 depots and a full rescue personnel of 30,000 organized into 3,000 squads.

Training for rescue squads will include special technical instruction and drill ranging over all classes of rescue problems and, in addition, practice in advanced first aid and handling of the injured. The medical division now has in press two publications, "Technical Manual for the Rescue Service" and

"Emergency Field Care and Transportation of the Injured," which will be used as training manuals. Advanced training in these subjects will be pursued after squad members are inducted into the U S Citizens Defense Corps. Preinduction training includes a basic course in first aid.

DUTIES OF STRETCHER TEAMS IN
EMERGENCY SERVICE

The medical division of the Office of Civilian Defense in an operations letter issued June 30 defines the duties of stretcher teams of the Emergency Medical Service. Rescue squads are now to assume the duties formerly assigned to the stretcher teams at major incidents with many trapped casualties. In addition to the technical work of rescue, this includes emergency care and transport of casualties from the scene of an incident to an ambulance or to a point where medical service is available. Stretcher teams remain, however, an essential part of the Emergency Medical Service. The functions of the teams as outlined in the new statement are as follows:

1. Assisting medical personnel at casualty stations in handling and nonprofessional care of minor casualties.
2. Unloading ambulances and assisting in reception of casualties at hospitals.
3. Performing rescue work at minor incidents not requiring specialized rescue squads.
4. Assisting rescue squads at major incidents at which many casualties are trapped.

A stretcher team is composed of a leader and four other persons, preferably men and older boys from the neighborhood of the facility to which they are attached. The medical division urges that members of a hospital staff who have maintenance functions should not be selected for duty on a stretcher team.

All team members must meet the requirements of OCD regulations for membership in the U S Citizens Defense Corps by completing either an American Red Cross or a Bureau of Mines first aid course. If a Red Cross or Bureau of Mines instruction is not available, instruction in first aid may be given by any other qualified person certified by the chief of Emergency Medical Service.

HEALTH OFFICIALS IN CIVILIAN PROTECTION ORGANIZATION

In order that health and sanitation may be maintained during and after an air raid, health officers, with their deputies, division chiefs and sanitary inspectors, should be members of the U S Citizens Defense Corps, the Office of Civilian Defense advises in Operations Letter No 131. Commanders of the U S Citizens Defense Corps are urged to appoint health officers to their staffs.

Health officers should develop plans for prompt action in emergencies to assure (1) maintenance of safe water, food and milk supplies, (2) sanitary disposal of sewage and putrescible wastes, (3) sanitation at mass feeding centers, rest centers, casualty stations, billets and other temporary facilities for war emergencies, and (4) control of communicable disease, the operations letter points out.

In communities in which the health department does not have sufficient staff to provide sanitary supervision and inspection services in a war emergency, the health officer may select volunteer health deputies and recommend their appointment to the staff unit of the Citizens Defense Corps. Tasks to which they may be assigned include supervision and inspection of disinfection of fractured water mains, pasteurization of milk, and preparation and handling of food at emergency feeding centers.

A section of the operations letter is devoted to the place of state health agencies in the civilian protection program. State defense councils are urged to obtain the guidance and leadership of the state health officer in the development of an emergency health and sanitation program throughout the state.

NURSES' AIDES ELIGIBLE FOR CIVILIAN SECURITY BENEFITS

All volunteer nurses' aides should be enrolled in the U S Citizens Defense Corps, the medical division of the Office of Civilian Defense states in a special announcement, Circular Medical Series No 32. The immediate importance of this announcement lies in the fact that nurses' aides must be enrolled in the Nurses' Aide Unit of the Citizens Defense Corps if they are to be eligible for the benefits provided under the War Civilian Security Program of the Federal Security Agency for all members of or trainees for the Citizens Defense Corps who may be injured in line of duty. Nurses' aides at present working in hospitals and health agencies are considered to be in training for service in care of the wounded in the event of an enemy attack or other wartime disaster. They are therefore eligible for membership in the Defense Corps and are thus eligible for the benefits of War Civilian Security after enrollment. It is suggested that the local chief of Emergency Medical Service and the local nurse deputy arrange with the Red Cross Nurses' Aide Committee to have the required CDC oath administered at the graduation ceremony. All nurses' aides who have completed their training since the program was initiated but have failed to enroll in the Defense Corps should now become enrolled members. Women who are still undergoing preliminary training as nurses' aides but have not yet graduated are also eligible for benefits if they are properly registered with the personnel officers of the appropriate Citizens Defense Corps as trainees for the nurses' aide unit.

MISCELLANEOUS

DR. RAYMOND W. WAGGONER APPOINTED CONSULTANT IN PSYCHIATRY

The Selective Service Bureau of the War Manpower Commission announced on July 21 the appointment of Dr. Raymond W. Waggoner as consultant and adviser in psychiatry to the director of Selective Service. Because of the large percentage of registrants who are rejected on examination for neuropsychiatric reasons it was considered of the utmost importance to have all pertinent data on registrants, which might be used for the guidance of psychiatrists at induction stations, assembled and forwarded to them by local boards. Dr. Waggoner will advise on psychiatric problems which will include methods of assembling such data. Dr. Waggoner graduated from the University of Michigan Medical School in 1924; he was formerly associate professor of neurology at the University of Michigan and has been professor of psychiatry and director of its Neuropsychiatric Institute since January 1937.

in addition to a required internship and for the associate medical officer grade (\$3,828) one year of internship. The salaries quoted include overtime pay. There are no written tests and no age limits. Persons now using their highest skills in war work should not apply for these positions. Appointments in federal positions are made in accordance with war manpower policies and employment stabilization plans. Before a definite offer of appointment is made, eligibles are cleared through the Procurement and Assignment Service for Physicians, Dentists and Veterinarians of the War Manpower Commission. Persons rated eligible on the medical officer examination of 1941 need not file applications again unless they consider that they now possess qualifications for eligibility in a higher grade or different option. Application forms may be obtained at first and second class postoffices, civil service regional offices and the commission in Washington, D C.

PHYSICIANS NEEDED FOR CIVILIAN WAR SERVICE

The shortage of physicians to engage in war work in the civilian branches of the government continues. This need resulted in a liberalized civil service examination for medical officers in 1941. The Civil Service Commission has just revised and reannounced this examination. The twenty optional branches under which doctors may apply range from General Practice to Aviation Medicine. Those appointed will perform professional duties as doctors of medicine in active practice in hospitals, in dispensaries in the field or in rural areas or in bureaus of the government. Doctors will also be used in industrial establishments under direction of the War Department. Applicants for all grades must have received the degree of M D from an accredited medical school. Applicants for the senior medical officer grade (\$5,228 a year) must have had at least five years of appropriate medical experience for the medical officer grade (\$4,428 a year) three years of experience

NYLON FILTERS FOR TRANSFUSION PURPOSES

A fine weave nylon cloth having 30,000 holes per square inch is being used by several laboratories as a filter during the processing of blood plasma for the Army and Navy. Small nylon bags have also been devised for filtering either plasma or whole blood during actual transfusions. Dr. S. Brandt Rose, chief of the bacteriologic laboratories of the Philadelphia General Hospital, announces in *Science* that the new type filters have been successfully employed in more than a thousand transfusions. Dr. Rose said that while it is desirable that fresh blood be filtered immediately before it is transfused, this precaution is mandatory when stored blood or plasma is used. The nylon fabric has several desirable characteristics as a filter. Dr. Rose states that no instance of sensitivity to nylon has been observed in more than a thousand blood and plasma transfusions made with the filters during the past eight months and no reactions have followed the administration of 1, 1/2, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20 cc's.

ORGANIZATION SECTION

OFFICIAL NOTES

MEDICAL SERVICE AND PUBLIC RELATIONS

Minutes of Meeting, July 21, 1943

The Council on Medical Service and Public Relations, Dr James E Paulin, President of the American Medical Association, presiding, met in the Board of Trustees Room at the headquarters of the American Medical Association.

There were present Drs A W Adson, Louis H Bauer, John H Fitzgibbon, W S Leathers, E J McCormick, James R McVay, Ernest E Irons representing Dr Roger I Lee, James E Paulin and Olm West, members of the Council, Mr J W Holloway, Director of the Bureau of Legal Medicine and Legislation, and Dr R G Leland, Director, and Mr A M Simons, member of the Staff, of the Bureau of Medical Economics. The President announced that Dr Roger I Lee and Brig Gen Fred W Rankin had found it impossible to be in attendance.

Dr West reported that he had taken the responsibility of communicating with members of the Council, assuming that they would wish to have a meeting for organization, the preparation of a budget and a consideration of the nature of the work to be undertaken.

Nominations were called for and Dr McVay nominated Dr Louis H Bauer, who was elected Chairman by unanimous vote.

Dr Bauer stated that he would try to do his utmost, realizing that the burden would be taken from his shoulders to some extent when a permanent secretary is secured. Most important was the selection of the right man for that purpose, who will be in Chicago and conduct the Council's work according to the suggestions of its members. Some had suggested that the Secretary be a physician. After the views of members were presented, Dr Bauer stated that the consensus was that the Council should try to secure a physician, if possible, if it is not possible to secure a physician, it will be necessary to get a competent layman with the proper medical point of view. Any physician secured should have the proper public relations point of view and any layman secured should have the proper medical point of view.

Consideration was given to salaries and budget.

The Chairman suggested that the Council propose a program before considering the budget. The functions of the Council as stated in the report adopted by the House of Delegates in June were read by Dr West. Dr Adson presented to each member of the Council proposed agenda. The discussion, in which it was suggested that committees be appointed to study some of these questions, continued until the Council recessed for luncheon.

The Chairman stated in the afternoon session that it seemed that two or three outstanding subjects on which to concentrate should be selected by the Council. He suggested the hospital-physician relationship, what approach the Council should make to the Wagner-Murray-Dingell bill, discussion of representation in Washington, and the relation of the Council to other organizations.

A committee of three members of the Council was appointed to consider the matter of securing a secretary. Consideration was given also to the budget. The committee members are Drs Bauer, West and McCormick.

The Chairman appointed Drs Adson, Leathers and McVay as members of a committee to determine the present status of work and a proposed program.

The Council voted to have another meeting on September 9 and 10.

Dr Adson asked the opinion of the Council as to what it thought about committees on medical service and public relations in state associations and component county societies. The consensus was that it would be better to ask these units which of their committees they desired to have as the outlet for the Council on Medical Service and Public Relations of the American Medical Association.

The Chairman felt that press relations were part of the work of the Program Committee and suggested that Dr Fitzgibbon could consider, in collaboration with the Program Committee, the manner in which the material of the Council can be filtered through.

Dr West stated that the Council might be of important help in that its members or others they might secure could appear before Congressional committees when necessary, he stressed the necessity of making the best possible selections for this purpose.

Dr Adson informed the Council concerning the work of the committee of the American Dental Association in Washington.

Dr West, in the discussion of the question of who would act as temporary secretary until the Council secured a permanent one, informed the Council that Mr Holloway, Director of the Bureau of Legal Medicine and Legislation, had agreed to act as temporary secretary if the Council so desired. Mr Holloway, on being asked by the Council, stated that he would be glad to serve as temporary secretary. It was moved by Dr McCormick, seconded by Dr Adson and carried, that Mr J W Holloway be asked to act as temporary secretary until a permanent secretary of the Council is secured.

Dr West presented several matters that had been received at the offices of the Association that might later come to the attention of the Council. No action was taken on any of these matters but they were referred to the Program Committee for consideration as to priority of action.

The Council adjourned at 4 30 p m.

SUMMER HEALTH HINTS

The next two programs for the series of broadcasts over WLS on Thursdays at 2 45 p m under the title "Summer Health Hints" will be as follows:

August 12 'Hiking'
August 19 "Hay Fever Time"

A new series of broadcasts on appropriate, timely, health topics is contemplated on station WLS beginning in early autumn.

WOMAN'S AUXILIARY

Pennsylvania

A recent meeting of the Philadelphia auxiliary was of unusual interest, as it was the first time that a combined meeting was held of the First Councilor District of the state medical society, Dr George C Yeager, councilor, and the First Councilor District of the state auxiliary, Mrs W Burrill Odenatt, councilor. Among the 100 guests present were Dr Gilson Colby Engel, vice president of the state medical society, Dr

William Bates, president of the Philadelphia County Medical Society, and Mrs Leon C Darrach, councilor of the Second District. The president, Mrs George C Yeager, introduced the officers and speakers. Dr Yeager presented certificates to sixteen physicians who have been in practice fifty years. Dr William Egbert Robertson spoke on "Fifty Years of Medicine." Dr Hubley R Owen, director of health of the city of Philadelphia, told of his recent trip to England, where he visited hospitals.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Personal—Charles H. Danforth, Ph.D., professor of anatomy at the Stanford University School of Medicine, San Francisco, has been appointed to the honorary position of librarian of the California Academy of Sciences.—Dr. Romeo R. Root, Riverside, among others, received a gold-headed cane in May in recognition of his long service in the Riverside County Medical Association.

Drugless Practitioners May Sign Death Certificates—Drugless practitioners may legally sign death certificates, according to an opinion released on June 23 by Attorney General Robert W. Kenny, newspapers reported. In Kenny's opinion given to the board of medical examiners, he pointed out that the California courts had never ruled on the legality of the question. In thus making it possible for the drugless practitioner to sign death certificates, it should of course be realized that the implication is not to be conveyed that such drugless practitioners may call themselves or advertise themselves as physicians or that they may practice medicine. A drugless practitioner receives his license from the board of medical examiners. By law the mode of treatment of human diseases, injuries and deformities employed by drugless practitioners is recognized. It is difficult for me to believe that a drugless practitioner in attendance on such a patient should not be qualified to file the certificate of death as well as the medical certificate.

COLORADO

Changes in State Medical Board—New officers of the Colorado State Board of Medical Examiners for the period July 1, 1943 to June 30, 1945 include Dr. B. Franklin Blotz, Rocky Ford, president; C. Robert Starks, D.O., Denver, vice president; and Dr. John B. Davis, Denver, secretary-treasurer. Membership of the board includes Drs. Blotz, Davis, George H. Gillen, Denver; Robert J. Groom, Grand Junction; Walter W. King, Denver; William P. McCrossin, Jr., Colorado Springs; George A. Unfug, Pueblo; C. Robert Starks, D.O., and Rodney Wren, D.O., Pueblo.

DISTRICT OF COLUMBIA

Physicians Organize Panel for Emergency Services—A panel of 338 physicians has been established for medical care during emergencies to be available through the medical bureau of the Medical Society of the District of Columbia. The physicians will respond to calls in any part of the city where their services are urgently needed and will report through the medical bureau which maintains a twenty-four hour switchboard and will cooperate with other physicians who have accepted the chairmanship of various sections of the city. The sections are divided to conform with those designated by the Selective Service System. The operation of the new setup is the result of a plan initiated several months ago (THE JOURNAL, March 6, p. 774). The announcement to the press was made by Dr. A. Magruder MacDonald, chairman of the committee on medical service for the district which includes representatives of seven medical and health agencies, namely the district medical society, the U. S. Public Health Service, the district health department, the Emergency Medical Service for Civilian Defense, the District Procurement and Assignment Committee, the Health Security Administration and the Medico-Chirurgical Society, which is made up of colored physicians. Out of the 338 physicians who volunteered to serve on the panels in the twenty-five selective service districts of the city, 189 are general practitioners and 128 are specialists who agreed to do general practice if necessary.

KANSAS

Dr. Crumbine Honored—In the first ceremony of its kind in history, the state of Kansas recently officially honored Dr. Samuel J. Crumbine. Jackson H. Hight, N.Y., who for many years served as secretary of the Kansas State Board of Health and is dean of the University of Kansas School of Medicine (THE JOURNAL, Nov. 28, 1942, p. 1050). The Crumbine plaque cast for presentation to Dr. Crumbine at a testimonial dinner in New York in 1942 was officially unveiled in the Topeka

Hall of Fame. A 'Dr. Crumbine Week' was officially declared throughout Kansas and the Missouri Pacific Railroad, the first railroad to abolish the common drinking cup, a movement launched by Dr. Crumbine, sponsored a publicity campaign throughout eleven states designating July as 'Dr. Crumbine Month.' According to the *Health Officer News Digest*, final preparations are under way to name a new train car 'The Dr. Crumbine.'

MASSACHUSETTS

License Revoked—The state board of registration in medicine on June 28 revoked the license to practice medicine in Massachusetts of Dr. Philip L. Manfredi, Boston, because of gross misconduct in the practice of his profession.

Rehabilitation Program for the Tuberculous—The executive committee of the Lynn Tuberculosis League has approved a rehabilitation program for Lynn residents with tuberculosis, including plans to employ a rehabilitation specialist. Five hundred dollars was also appropriated to provide educational and vocational scholarships for persons with tuberculosis ineligible for such vocational aid from governmental sources and will be available to those at home who have never needed sanatorium care as well as to those who have taken sanatorium treatment. It is planned for the tuberculosis specialist to begin work sometime in September, allowing a period for specialized training under the direction of the National Tuberculosis Association.

MINNESOTA

License Restored—The license to practice medicine of Dr. Arthur H. Langhoff, Glencoe, which was suspended by the state board of medical examiners Feb. 13, 1942, was restored by the board on May 7.

Personal—St. Olaf College, Northfield, recently conferred the honorary degree of doctor of laws on Dr. Donald C. Baltour, director of the Mayo Foundation for Medical Education and Research, Rochester, and the honorary degree of doctor of science on Dr. Adolph M. Hanson, Faribault, in recognition of work on the isolation of the active principles of various hormones. Dr. Baltour was also recently elected an honorary fellow of the Royal Society of Medicine.—Dr. Theodor E. Bratrud, Minneapolis, recently received an alumni award of the Marquette University School of Medicine, Milwaukee, for a paper submitted at an alumni clinic entitled 'Congenital Adrenal Hyperplasia.'

NEW JERSEY

State Medical Election—Dr. Joseph F. Londrigan, Hoboken, was chosen president-elect of the Medical Society of New Jersey at its recent annual meeting in Newark. Dr. Ralph K. Hollinshed, Westville, was installed as president to succeed Dr. Elias J. Marsh, Paterson. Dr. Alfred Stahl, Newark, is the secretary.

Endowment Fund for Research—Acting on the suggestion of Dr. Elias J. Marsh, Paterson, president of the state medical society in 1943, members of the society have been submitting contributions to establish an endowment fund for the support and encouragement of original investigations conducted by members. At the present time the fund has four \$100 war bonds and almost enough cash to purchase the fifth. In his proposal to the house of delegates to create a scientific research fund, Dr. Marsh said: 'This will compensate for the lack of any generally available teaching or research institution in our state. We have in New Jersey plenty of ability, plenty of scientific spirit and plenty of clinical and other material to produce good original work, but we lack facilities for bringing them together in a practical and fruitful way.'

NEW YORK

License Restored—The state board of medical examiners at a meeting on June 18 restored the license to practice medicine in New York of Dr. Julius Hammer, Scarsdale.

Personal—Donald K. Tresler, Ph.D., since 1933 chief of research and head of the division of chemistry, New York Experiment Station, Geneva, has joined the staff of the General Electric Company. He will be concerned chiefly with research on refrigeration and the freezing preservation of food, working in the laboratories at Bridgeport, Conn.—Alfred E. Sherrill, Ph.D., plant superintendent, has been elected vice president of Winthrop Chemical Company, New Haven.—Dr. Walter B. Martin, warden of Clinton Prison at Dannemora, has been appointed warden of the Alca Prison effective July 1.

New York City

Education Program to Obviate War Shock in Seamen—A medical education program under the auspices of the United Seamen's Service and the War Shipping Administration to help merchant seamen avoid war shock will be started under the direction of Dr Florence B Powdermaker, the New York Times reported on July 9. The program will be supervised by the U S Public Health Service.

Promotions at Rockefeller Institute—The Rockefeller Institute for Medical Research announced the following promotions on its scientific staff: assistant to associate, Merrill W Chase, Ph D, Stanford Moore, Ph D, Isabel M Morgan, Ph D, Howard A Schneider, Ph D, and William H Stein, Ph D, fellow to associate, D Wayne Woolley, Ph D, and fellow to assistant, Dr Sidney Rothbard.

Three-Cents-A-Day Plan Expanded—On July 19, 257 member hospitals of Associated Hospital Service of New York approved a plan of expanded service for the 1,365,000 members of the Blue Cross three-cents-a-day plan. In addition to providing hospital bed and board, prescribed diets, general nursing care and anesthesia when administered by a hospital employee, Blue Cross members who occupy semiprivate accommodations may now use the operating room as often as necessary, the former \$25 limitation being removed. All x-ray examinations consistent with the treatment required will be provided, the \$25 limitation being waived. Laboratory examinations, formerly held to \$20, are now limited only by the need. All drugs and medications are now provided, as are all dressings and plaster casts. The use of the cystoscopic room, cardiographic equipment and physical therapeutic equipment are made available at no added cost, as are basal metabolism tests. After twenty-one days of hospitalization members receive a 50 per cent discount for an additional period up to ninety days on all regular hospital charges, including the services listed. The rate of payment to hospitals has now been increased to compensate them for this more comprehensive service. An extra allowance is likewise provided for those members who wish private room accommodations. Another phase of the new program is the making available individual memberships to men and women under 60 years of age who cannot enroll through a place of employment.

NORTH CAROLINA

Dr MacNider Retires as Head of Pharmacology Department—Dr William deB MacNider, Kenan research professor of pharmacology and head of the department at the University of North Carolina School of Medicine, Chapel Hill, will relinquish his responsibilities as head of the department on September 1. He will continue in the department as research professor. Dr Grant L Donnelly has resigned as associate professor of pharmacology in order to resume the practice of medicine.

New Hospital for Early Treatment of Venereal Diseases—The North Carolina State Board of Health has accepted an offer made through the Federal Works Agency for \$210,200 annually to establish in Charlotte a hospital for the intensive treatment of venereal diseases in the early stages. The board signed a lease with the Palace Realty Company of Charlotte whereby the Charlotte Sanatorium is to be used for the purpose. About 200 patients can be accommodated at one time. The U S Public Health Service will provide a chief medical officer, a chief nurse and a record analyst. The Zachary Smith Reynolds Foundation has given \$25,000 to the board to be used in establishing a closer administrative supervision throughout the state.

PENNSYLVANIA

Personal—Dr Anthony J Sparta has been named health officer of Easton, succeeding the late Dr Reuben S Raub, who died, May 28.—Dr Eugene L Stelke, formerly assistant superintendent of the Philadelphia State Hospital, is now superintendent of the Danville State Hospital, Danville.

Philadelphia

Pharmacologic Changes at Sharp and Dohme—Arnold D Welch, Ph D, who, since June 1940 has been in charge of the pharmacologic research laboratories of the medical research division of Sharp and Dohme, has been made director of research of the division. According to *Science* he will continue to direct the general activities of the pharmacologic and nutritional laboratories. Dr Karl H Beyer, who recently joined the medical research division, has been named assistant director of phar-

macologic research. Paul A Mattis, D Sc, who is supervising the histologic and toxicologic work of the department, will serve as assistant department manager.

Changes in the Faculty at Jefferson Medical College—Dr Paul C Swenson, associate professor of radiology at the Columbia University College of Physicians and Surgeons, New York, has been appointed professor of roentgenology at Jefferson Medical College of Philadelphia and Dr James Rudolph Jaeger, assistant professor of surgery (neurosurgery), University of Colorado School of Medicine, Denver, has been appointed professor of neurosurgery. Other appointments to Jefferson include those of Dr William G Sawitz, assistant professor of parasitology, Dr Joseph Stasney, assistant professor of pathology, and Dr Francis M Forster, assistant professor of neurology.

Alvarenga Prize Goes to Ernest Faust—On July 14 the College of Physicians of Philadelphia awarded its Alvarenga Prize to Ernest C Faust, Ph D, professor of parasitology and acting head of the department of tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans, for his "outstanding contribution to our knowledge of parasitology and tropical medicine." This prize was established by the will of Pedro Francisco Da Costa Alvarenga of Lisbon, Portugal, an associate fellow of the College of Physicians, to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883, to the author of the best memorial on any branch of medicine which may be deemed worthy of the prize.

RHODE ISLAND

Mr Farrell Becomes Executive Secretary of State Society—On July 1 Mr John E Farrell, executive secretary of the Providence Medical Association for the past five years, became executive secretary of the Rhode Island Medical Society and managing editor of the state medical journal. The executive office of the society and the business office of the journal will be maintained at 106 Francis Street, Providence 3. Mr Farrell will continue as executive secretary for the Providence Medical Association (THE JOURNAL, June 5, p 388).

SOUTH CAROLINA

Crippled Children's Home Transferred to State—The Florence County Crippled Children's Home was formally transferred to state ownership during special ceremonies on July 1, the result of a special act of the legislature. Under state management the unit will be known as the South Carolina Crippled Children's Convalescent Home and is said to be the first state-owned convalescent home in South Carolina. Located on a 6 acre tract on the Florence Timmons Highway, the home, established in 1937, consists of two large buildings, one for white children and one for Negroes, connected with a smaller building which houses the central kitchen and heating plant. It is equipped with a modern swimming pool and has a capacity of 50 beds and cribs. Beginning on August 1 the home was to be equipped and staffed for physical therapy treatments. News papers report that the home will be operated under the division of crippled children under the state department of health, which is under the direction of Dr George S T Peebles, Columbia. Dr James A Hayne, Columbia, state health officer, in his speech of acceptance stated that Dr Peebles would be advised by a subcommittee of the state board of health's executive committee composed of Drs Walter R Mead, Florence, William R Wallace, Chester, and William L Pressly, Due West.

TENNESSEE

Changes in Health Officers—Dr Harcourt A Morgan Jr, Lewisburg, head of the Bedford County Health Unit, has been placed in charge of a seven county area including the six adjacent counties of Grundy, Franklin, Warren, Bedford, Marshall, Moore and Coffee with headquarters at Manchester.—Dr Chester A Hicks, Elizabethton, director of the health unit of Carter, Johnson and Unicoi counties, has resigned to become director of health of the city of New Rochelle, N Y.—Mr Lowell H Stokes, McMinnville, in charge of the Warren County Health Department, has been appointed to a similar position in Knox County.

Physician Honored—Dr Edward C Ellett was guest of honor at a dinner recently, given by the Memphis and Shelby County Medical Society to honor his completion of fifty years active practice in Memphis. In 1939 Dr Ellett was awarded the Leslie Dana Medal through the National Society for the Prevention of Blindness and in 1942 he received the award of merit from the American Academy of Ophthalmology and Otolaryngology.

gology in recognition of his services as president and member of the council Dr Ellett was secretary of the Section on Ophthalmology of the American Medical Association 1900-1901 and chairman of the Section 1914-1915 and is a past president of the American Ophthalmological Association

TEXAS

New Home of State Health Department—An open house on July 26 formally marked the installation of the Texas State Department of Health in its new building at 400-412 East Fifth Street, Austin. The structure was made possible by a grant of \$135,105 from the federal government and \$87,500 from the state of Texas. A joint resolution by the forty-seventh legislature authorized the state board of health to proceed with final arrangements. Ground breaking ceremonies were held on March 9 1942. Because of labor and material shortages the work was held up at various times and it was not until June 18 of this year that the keys were formally turned over to the state department of health. The building is constructed entirely of reinforced concrete. The right wing is the original laboratory, to which one floor was added to be used for making biologic preparations. The left wing of the building is entirely new. The basement will contain the division of vital statistics, where fireproof vaults have been constructed in which to keep these records. On the first floor will be the offices of the state health officer, central administration, hygienic laboratories and local health services. The second floor will contain offices of sanitary engineering, public health education, central filing room, malaria control, tuberculosis control office of civilian

Texas State Department of Health.

defense and bedding division. On the third floor will be located the division of maternal and child health of the state board, library, venereal disease control, the food and drug division, and milk inspection, public health nursing and dental division. The new part of the building is 151 feet in length and 60 feet in depth and covers one-half block of land. Now for the first time since its inception, the state department of health will be all at one location permitting better administrative policies with work under the direct supervision of the state health officer, Dr George W. Cox.

WASHINGTON

New Health Activities in King County—The enactment of recent legislation has made possible the expansion of the health program in King County. Under the direction of Dr Wallace W. Schwabland, Seattle, health officer of the county, the appointment of Dr Bryan Newsom, Seattle, for many years epidemiologist of Seattle, marks the beginning of a division of epidemiology in the department of health. Under a reorganization the King County commissioners have designated the county health officer to be tuberculosis administrator for the county, which means that admission of patients to the county tuberculosis institutions will be decided finally by the health officer rather than by the medical director of the sanatorium.

WEST VIRGINIA

Members of Public Health Council Reappointed—Drs. William R. Goff, Parkersburg, William P. Bittinger, Summerlee, and Walter E. Vest, Huntington, have been reappointed by Governor Matthew M. Neely as members of the Public Health Council for the term ending June 30 1947. Dr Vest has been a member of the council since 1933 and president since

1937. Dr Goff has been a member since March 1942, and Dr Bittinger is beginning his second four year term, having first been appointed in 1939. Dr John E. Offner, Weston, recently appointed state health commissioner, is a member and ex officio secretary of the council. The next meeting of the council will be held in Charleston, October 25-27.

GENERAL

Mead Johnson Continues Award for Vitamin B Research—Mead Johnson and Company has renewed the arrangements for a period of five years whereby the annual award of \$1,000 will be given for research dealing with the vitamin B complex. The recipient of this award will be chosen by a committee of judges of the American Institute of Nutrition.

American Medical Association Membership Waived in Orthopaedic Board Requirements—The American Board of Orthopaedic Surgery has ruled that membership in the American Medical Association is not necessary for those who wish to present themselves for part I of the examination by the board. Dates for part I are as follows: New Orleans, October 8-9, New York, October 15-16, Chicago, October 22-23 and San Francisco, October 29-30. The board had earlier sent out a notice to most prospective applicants that membership in the American Medical Association would be prerequisite and essential.

Expand Program of Physical Education—Harold T. Friermood, Dayton, Ohio, has been appointed special secretary of health and physical education of the National Council of the Young Men's Christian Associations of the United States of America. He will aid in redirecting the group's program in relation to physical fitness, health education, swimming and water safety and in devising methods of enlisting volunteer and part time leadership for service in communities where staffs have been depleted by transfer of Y M C A secretaries and physical directors to other forms of service. Mr Friermood has been given a leave of absence as director of physical education of the Dayton Y M C A to undertake this special service for the National Council.

Special Society Elections—Dr Albert A. Berg, New York, was chosen president-elect of the International College of Surgeons at its recent meeting in New York and Dr Desiderio Roman, Philadelphia, was installed as president. Vice presidents are Drs Manuel A. Manzanilla, Mexico, D. F., Herman de las Casas, Caracas, Venezuela, Custis Lee Hall, Washington, D. C., Ratael Angelo Calderon Guardia, San Jose, Costa Rica, Ali Ibrahim Pascha, Cairo, Egypt, and Alejandro Ceballos, Buenos Aires, Argentina. Dr Max Thorek, Chicago, is secretary. At the annual meeting of the executive board of the National Gastroenterological Association the following officers were reelected for the coming year: Drs Anthony Bassler, New York, president, Clarence J. Tidmarsh, Montreal, Harry M. Eberhard, Philadelphia, and William W. Lermann, Pittsburgh, vice presidents; Roy Upham, New York, secretary general, national council; G. Randolph Manning, New York, secretary, and Elihu Katz, New York, treasurer.

The Poliomyelitis Situation—The U. S. Public Health Service reported on July 28 that the incidence of infantile paralysis had reached epidemic proportions in several Southwestern states and that figures for the country during the first six and a half months were the highest in twelve years. The New York Times reported on July 29 that a sharp rise in the number of cases since early June was accounted for by outbreaks in Texas, California and Oklahoma. No specific cause could be assigned for the situation; it was stated and no predictions could be made as to the possibilities of a further spread. Figures for the week ended July 17 showed 297 cases in the United States as compared with 245 for the preceding week. 231 cases or 94 per cent, were reported from three states: Texas which had 102, California 90 and Oklahoma 39. During the first week in June Texas reported 6 cases, California 35 and Oklahoma none. Arizona reported 3 cases for the week ended July 17 but recorded 45 for the first half of the year. Previous to July 17 no state other than those four had reported more than 6 cases in any week this year but in the latest report New York announced 11 cases as compared with 5 the week before and both Kansas and Arkansas had 7 each. For the first twenty-eight weeks of this year 1,020 cases were listed for the entire country. The Times also reported that Hawaii is fighting infantile paralysis—47 cases have been treated in three months with 5 discharged as cured. The Times stated on July 17: "Never before had Hawaii more than a few scattered cases." The report said: "At the time of this report 40 patients are still under treatment in the special hospital set up for the purpose."

Foreign Letters

LONDON

(From Our Regular Correspondent)

June 26, 1943

An Industrial Health Advisory Committee

At a conference in London Mr. Ernest Bevin, minister of labor, described the setting up of an industrial health advisory committee attached to his department. He said that in the past industrial health had been rather relegated to a separate compartment. The ordinary physician had not much knowledge of the conditions of industry and tended to regard industrial health as a matter for the specialist. But there had been great improvement during the war. The services of many part time works physicians had been enlisted and liaison made between works physicians and outside medical services. The great trouble was shortage of physicians. The employer naturally sought to get the utmost out of his machines, but he had also to study the human factor. It had been found, rather paradoxically, that a slight slowing down of the rate of production actually increased production. When machines were working at their full capacity the nerve strain was great and there was so much "standing off" and introduction of new workers on account of the exhaustion of those whom they replaced that better results were obtained by some slowing down.

Another important factor was the development of safer materials and methods and more effective safeguards. Thus the discovery of a harmless substitute for yellow phosphorus in the manufacture of matches, the introduction of leadless pottery glazes and the substitution of solvents less toxic than benzene and carbon disulfide in rubber cements were valuable advances. The duty of the new committee would be to keep step with every discovery so that the best possible use could be made of it. He believed that methods of lighting and ventilation were still in their infancy and that great improvements now used for war purposes would in time be adopted in industry in general. The committee would also concern itself with nutrition, and he was anxious that the present wartime feeding arrangements would be continued after the war, because they had been shown to be great checks against industrial ill health.

The machinery of inquiry (as distinct from research) into industrial health questions would be developed by increasing facilities for x-ray examinations, examination of blood samples and medical supervision of particular cases of illness. He believed that after the war one of the qualifications for managing factories would be a knowledge of and interest in industrial hygiene.

The chairman of the committee will be the minister of labor. Its members will comprise the chief inspector of factories, Sir Wilfred Garrett, the superintendent of the engineering department of the National Physical Laboratory, Mr. D. L. Smith, the deputy chief medical officer of the Ministry of Supply, A. J. Amor, the regius professor of medicine, Oxford University, A. W. Ellis, the chief medical officer of the Ministry of Health, Sir Wilson Jameson, the president of the Royal College of Physicians, Lord Moran (formerly Sir Charles Wilson) and John A. Ryle, Nuffield professor of social medicine, Oxford.

American Medical Officers in London

In the medical sphere this war has brought American physicians and surgeons into closer contact with British leaders and their work than ever before. The numerous American medical officers now in this country take part in the discussions before our medical societies and attend the clinics of the leaders of British medicine and surgery. Courses of one week each have been planned with the object of showing any American medical officer who is interested the working of the London hospitals and also some of the "sights of London." They come from all

parts of the country and are billeted in London. Facilities have been offered by such great hospitals as Guy's, the London, St. Mary's and the Middlesex. At Guy's visits are paid to the tomb of the founder, the bookseller Thomas Guy, to the museum and library and to the accident room. They are also shown the new pathology building and the outpatient department with its new appointment system.

On the occasion of the principal public function of the Royal College of Surgeons, the triennial Hunterian Oration, Col. Elliott C. Cutler, professor of surgery at Harvard, and Prof. W. G. Penfield, neurosurgeon at McGill University, were admitted to honorary fellowship. In the presence of most of the principal London surgeons they were presented to the president by the senior vice president, who described their achievements. These two surgeons will take part in the forthcoming Anglo-American surgical mission to Russia. During the mission the senior vice president of the college, Admiral G. Gordon-Taylor, will admit to the honorary fellowship two Russian surgeons, Dr. N. N. Burdenko, director of the Operative Surgery Institute, Moscow University and surgeon in chief to the Red Army, and Dr. S. Y. Yudin of the Sklifasovskii Hospital for Traumatic Diseases, Moscow. The British members of the mission will include Major Gen. D. C. Monro, professor of military surgery at the Army Medical College, Mr. E. Rock Carling and Mr. R. Watson-Jones. The object of the mission is to study the results of war surgery in Russia and to explore the possibility of extending medical relations between the two countries.

War Casualties for the First Three Years

In the House of Commons the government gave figures for the casualties of all the forces of the British Empire during the first three years of the war (excluding deaths from natural causes). They amounted to 514,993, of which 92,089 were killed, 226,719 were missing, 88,294 were wounded and 107,891 were prisoners of war. These figures do not include the casualties of the merchant service or other civilian casualties. Because of the failure of the Japanese to notify the names of prisoners as prescribed by international law, the number of prisoners in the Far East of Indian and colonial units is not exactly known.

The fact that the figures for those killed are higher than the figures for those wounded is susceptible of explanation. In the Royal Navy this is almost always the fact because of the nature of operations. The same is true of the Air Force, whose operations are almost entirely offensive and over enemy territory, as a result of which many wounded casualties inevitably become prisoners of war.

Civilian casualties for the same period were high as a result of bombardment of towns from the air. These were 47,291 killed and 55,643 injured, a total of 102,934.

Tracing Missing Civilians

Three years ago the Foreign Relations Department of the Red Cross was set up here to make inquiries for missing civilians of all nationalities in enemy or enemy occupied territory, so that relatives and friends could maintain contact with them by a message scheme. From a handful of people the staff has grown to over 300. Of 26,000 messages sent out by the department last month only 818 came back because the address could not be traced. Inquiries for missing civilians and for foreign soldiers, sailors, airmen and merchant seamen are made. Interned British civilians in Europe and interned as well as noninterned civilians in the Far East are covered. In exceptional cases of severe hardship medical supplies are sent. Sometimes visits of inspection are arranged and reports of them sent to relatives in this country. The Red Cross message of twenty-five words costs 24 cents to send and receive a reply. Fourteen languages are permitted.

The German and Italian governments have officially recognized this message scheme. By the end of the third year of

the war the index records held over 250 000 cards, and success in handling these inquiries was over 92 per cent. Last month 141 000 messages were received from abroad. Medical supplies have been sent to a Czechoslovak unit in Russia. Drugs and medical supplies have also been sent to Latvia to be distributed by the German Red Cross. As far as can be ascertained, this has always kept truth. The department has done more for merchant seamen of allied countries than for any other group. It has extended the Red Cross cloak of comfort to the tortured minds of people who have suffered by the occupation of their countries.

Oxford University Honors Dr Trueta

Dr Joseph Trueta, the Spanish surgeon famous for his treatment of war wounds, has been given the honorary degree of DSc by Oxford University. During 1930-1939, when civil war was waged in Spain and Barcelona was subjected to some three hundred and fifty air raids, he developed his method and applied it in the treatment of 20 000 wounded soldiers. It consisted in enclosing the wound in plaster of paris and relying on the rest so obtained to ensure healing instead of on antiseptics. This is known as the closed plaster treatment and gave him excellent results. It contrasts with the frequent dressing of wounds in the last great war. In 1939, after the defeat of the Spanish republicans, he came as a refugee to England where he published his book "Treatment of War Wounds and Fractures". During the present war, in 1940 he was appointed by the government adviser of the minister of health to the Wingfield-Morris Orthopedic Hospital. In presenting him for the degree the public orator's deputy Mr J G Barrington-Ward described Trueta's treatment as the enclosing of the wound in plaster of paris and the cutting off of bacteria from the main blood stream. He also spoke of the gentleness of his hand and heart. The ancient Romans gave the civic crown to a man who had saved in battle the life of one citizen: the university was right in placing its crown on the head of the man who had saved the lives of so many.

Suicides

The new statistics show a sharp rise in the number of suicides. They numbered 7 647 in 1942, 6 222 in 1941, 6 104 in 1940 and 6 387 in 1939. Yet it is the experience of most belligerent countries in this and past wars that suicides decrease during hostilities. This has happened in Britain during the present war and in Germany the number fell in 1940. But the last quarter of 1942 showed a rise of 87 per cent (to 2 538) over the same quarter of 1940. It does not seem that political murders or suicides in concentration camps are included in the German official statistics or that suicides of imported workers are included.

All the death rates for the large cities are likely to underestimate the actual rise in mortality for several reasons. The evacuation of children, mothers and expectant mothers to rural areas might be expected to reduce the number of deaths in the cities. As the official figures relate only to civilians, the transference of large numbers of adolescents to the armed forces would reduce the civilian population exposed to the risk of tuberculosis.

Soya in Sausages

The war shortage of certain foods, particularly meat, has led to various alternatives. The wartime sausage is much eaten but has the disadvantage of containing less meat and more bread. The latest innovation in food is the use of the soya bean as an ingredient in the sausage. In future the sausage will be composed of 37.5 per cent meat, 75 per cent soya and 55 per cent flour and water. The Ministry of Food states that it is impossible to make more meat available for sausages but as the protein value of soya is about three times that of meat, the protein content of sausages will be equal to what it was before the war.

AUSTRALIA

(From Our Regular Correspondent)

June 22, 1943

Social Trends in Australian Medical Practice

Of the various schemes for an Australian medical service, those receiving most attention are (a) national health insurance with medical benefits, (b) the plan of the Federal Council of the British Medical Association, (c) the New Zealand scheme, (d) the National Health and Medical Research Council's outline for a salaried medical service and (e) the scheme of the Victoria branch of the British Medical Association in Australia.

The main features of the National Health Insurance and Pensions Act have been outlined in a previous letter.

THE FEDERAL COUNCILS SCHEME

The Federal Council of the British Medical Association in Australia consists of two representatives from each of the various state branches. It has no power to bind the state branches by its decisions but functions as a coordinating body through which their opinions can be ascertained and expressed and as a medium for communication with the federal government on behalf of the branches collectively. The first mention of planning by the Federal Council of a general medical service for Australia is found in a report of a meeting of the council in February 1940 when consideration was given to the proposal that the British Medical Association should have as its policy the provision of a general medical service for Australia. A subcommittee was appointed to consider the question and the report drawn up by this committee was finally adopted by the Federal Council in September 1941. The report constitutes an outline of general principles rather than a practically detailed plan for a general medical service. Constant emphasis is placed on the personal relationship between doctor and patient and the right of free choice of a doctor by the individual. The basic principle is that health insurance is a practicable method of providing a complete general medical service and should be divorced from any scheme for the provision of cash benefits, such as sickness benefits and pensions. All persons having an income of less than £417 per annum should be compulsorily insured and thereafter receive medical services from a general practitioner of the individual's own choice to whom would be available all necessary ancillary and specialist services. The necessary capitation fee is not stated nor are details given of the system under which the practice would be conducted but apparently an extension of the practice or the lodge type is envisaged. The scheme has been criticized in that (1) the doctor is placed on a twenty-four hour working basis with no allowance for sickness or holidays, (2) no provision is made for epidemics or other emergencies arising within the scheme, (3) under the capitation system of payment the doctor would tend to take the maximum number of patients to make a living and would have little time to devote to the individual and (4) methods of consultation with specialists are cumbersome and in order to obtain the extra financial return given for specialist services the practitioner would be tempted to undertake work for which he did not have the necessary skill and experience. The apparent advantage of the scheme is that disturbance of present methods of practice would be minimal.

War Medicine and Surgery

In previous war periods the study and practice of war medicine and surgery has constituted the special province of medical members of the fighting forces. But under present conditions of total warfare when the civil population is directly threatened it has become a topic of major importance for every medical practitioner in the country. Accordingly the National Health and Medical Research Council has appointed a committee for the survey of war medicine and an associated junior research

fellow for the purpose of collecting, condensing and presenting reliable information on the subject. At regular fortnightly intervals the committee publishes an article in the form of a supplement to the *Medical Journal of Australia*. These articles cover a wide range of subjects related to problems of war surgery and medicine, and special emphasis is laid on practical experiences rather than on theoretical discussions. This work should achieve much in giving the medical men in Australia a concise and reliable account of recorded experiences in war medicine and in fitting them to meet medical emergencies affecting the civilian population.

BRAZIL

(From Our Regular Correspondent)

June 25, 1943

Anophelines of the Amazon Basin

The importance of the Amazon basin for the production of rubber to be sent to the United States has led to an extensive plan of sanitation which is being carried out by the American and the Brazilian governments. As the main problem is malaria, the recent studies by Brazilian sanitarians in this field are of great value. A case in point is the study reported by Drs. Ayrosa Galvão and Marques Porto on the biology of *Anopheles darlingi* and *Anopheles tarsimaculatus*, which are the anophelines with epidemiologic importance in the vicinity of Belém, the largest city of the basin, with a population of 208,000, at the mouth of the Amazon. The facts concerning the biology of the adults of these two species were observed between October 1941 and June 1942. *A. darlingi* practically occurs only in relatively high lands, which are not flooded by the tide, and where there is fresh water with low chloride content. *A. tarsimaculatus* is chiefly found in breeding places with relatively high chloride concentration, on the low lands invaded by the tide. The average number of *darlingi* mosquitoes captured per hour indoors and outdoors, with human and animal baits, was 0.96 and 0.98 respectively. The ratio of these numbers is very nearly 1 to 1 and *A. tarsimaculatus* gave respectively 1.6 and 7.6 per hour, the rate being 0.21 to 1. If we compare this figure (0.21) with 1 for *darlingi*, the rate at which *A. tarsimaculatus* frequents houses is five times smaller than that for *darlingi*. However, as *A. tarsimaculatus* is 4.8 times more abundant than *A. darlingi*, they had almost even chances of attacking man inside houses during the period of observation. The hourly rate of house captures from October 1941 to June 1942 showed that the prevalence of *A. darlingi* from December to June was small in comparison to that of *A. tarsimaculatus*, which was then very abundant, with a maximum during March. The study of the variation of the number of specimens captured during the night indoors showed that *A. darlingi* is nocturnal in its habits: most specimens enter the houses after 10 p. m., and at later hours they continue at a slightly lower rate until 6 a. m., 1 per cent of the total number of *A. darlingi* having been caught between 6 and 7 p. m., and 51 per cent after midnight. Diurnal captures made in the same houses showed that *A. darlingi* is relatively abundant until 8-9 a. m. Seventy-one per cent of *A. tarsimaculatus* enter houses before midnight, mostly from 7 to 8 p. m. Diurnal captures were very few. House captures made in three different places showed that the prevalence of *A. darlingi* in dwellings varies as new breeding places are formed. In places where *A. darlingi* was very prevalent these mosquitoes made up 94.8 per cent of the anophelines captured inside houses, while in outdoor captures with human bait their proportionate number fell to 70.1 per cent and with horse bait to 16.9 per cent. Nevertheless it seems that *A. darlingi*'s preference for food varies with the seasons, as precipitin tests made during this time, which was not favorable to its development, gave a human blood index of 15.2 per cent. It is the author's opinion that many more tests must be made before a conclusion can be reached.

Brief Items

In the new Pathologic Institute of the Santa Casa de Misericórdia Hospital of Rio de Janeiro, created a few months ago, Dr. Oswaldo Penna of the Oswaldo Cruz Institute is giving a postgraduate course on "Clinical Pathology of Malignant Growths." Twenty physicians from the interior of Brazil are taking this course.

In July Dr. Almeida Prado, professor of medicine at the São Paulo University, will begin to give a special postgraduate course in "Gastroenterology" at the Santa Casa de Misericórdia Hospital of Rio de Janeiro.

Dr. João Baptista Canto, surgeon of the Rio de Janeiro Department of Hospitals, died recently at the age of 56. Graduated in 1911, he went immediately to Europe, where he worked in several hospitals, especially in France. In 1914 he took a course of war surgery under Professor Gosset in Paris. Back in Rio de Janeiro he entered the service of the city administration in the Department of Hospitals, in which for some time he was head surgeon of the Municipal Emergency Hospital.

Dr. Antonio Alencar, professor of dermatology and leprology at the Minas Gerais University, died in Belo Horizonte at the age of 60. He contributed much to the development of the control of leprosy in the state of Minas Gerais, one of the most important foci of the disease in Brazil.

Dr. J. Oliveira Santos died a few days ago in Rio de Janeiro. He was head of the medical department of the Brazilian Sports Confederation.

Dr. Alvaro C. Carvalho, professor of medicine at the Bahia Medical School, died in Salvador, state of Bahia, at the age of 63.

The Death of Dr. Arthur Neiva

Dr. Arthur Neiva, head of the Division of Entomology at the Oswaldo Cruz Institute, died in Rio de Janeiro on June 6 at the age of 63. Dr. Neiva was one of the first assistants of Oswaldo Cruz in 1906 at the time of the foundation of the Institute at Manguinhos, a suburb of Rio de Janeiro. In his paper "A Strain of Malaria Parasite Resistant to Quinine," published in 1910 in the Archives of the Oswaldo Cruz Institute, he gave, perhaps for the first time, the explanation for the failure of quinine to protect against malaria under certain conditions. A few years later he was invited to organize the department of medical zoology and parasitology of the Bacteriologic Institute of Buenos Aires. He went also to Washington to write, in collaboration with L. O. Howard, an important monograph on insect vector of diseases. He described many new species of arthropods of South America, particularly mosquitoes, and his name is used in the parasitologic nomenclature to designate several species.

Marriages

- STANFORD S. KROOFF, Los Angeles, to Miss Barbara Williams of Waban, Mass., at Miami Beach, Fla., July 17.
JOSEPH C. MANNING JR., Savannah, Mo., to Miss Helen Elizabeth McDougale of Rochester, Ind., recently.
GEORGE TURNER HOWARD JR., Knoxville, Tenn., to Miss Joan Lucey of Forest Hills, N. Y., June 26.
FRANK BUIST WOODRUFF, Woodruff, S. C., to Miss Martha Thelma Courtney of Aiken, June 25.
JEFFERSON EUGENE MORRIS, Moultrie, Ga., to Miss Roberta E. Haggerty at Augusta in June.
CHARLES S. BAER, Steger, Ill., to Miss Adelaide Ascher of Chicago Heights in June.
BRUCE AMBLER, Abington, Pa., to Miss Marian Jane Law of Altoona in June.
RAYMOND M. GALT, Chicago, to Miss Jane Falley of Alton, Ill., recently.

Deaths

Frederic Vinal Hussey ☉ Providence, R I, Columbia University College of Physicians and Surgeons New York 1904 past president of the Rhode Island Medical Society, member of the New England Surgical Society, fellow of the American College of Surgeons, state regent of the International College of Surgeons at Geneva, specialist certified by the American Board of Surgery and a member of the founders group, served as a lieutenant in the medical corps of the U S Naval Reserve assigned to duty at Navy Base Hospital number 4 at Queenstown, Ireland, and Base Hospital number 5 at Brest, France, during World War I since 1934 lieutenant commander in the medical corps of the U S Naval Reserve organizer of unit number 5, in March 1940 was transferred to the honorary retired list recently a member of the Rhode Island Committee of the Procurement and Assignment Service senior surgeon to the Memorial Hospital, Pawtucket, from 1910 to 1940, when he became chief of the surgical staff surgeon in the outpatient department of the Rhode Island Hospital from 1907 to 1919, assistant surgeon from 1919 to 1929 and since 1930 consulting surgeon consulting surgeon to the Miriam Hospital Providence, Westerly (R I) Hospital, Providence Lying-In Hospital, Notre Dame Hospital, Central Falls and the South County Hospital Wakefield, aged 64, died, June 15, of pancreatitis

John Milton Griscom ☉ Moorestown, N J University of Pennsylvania Department of Medicine Philadelphia, 1906 emeritus professor of ophthalmology at the Medico-Chirurgical College, Graduate School of Medicine University of Pennsylvania, Philadelphia, specialist certified by the American Board of Ophthalmology, member of the American Academy of Ophthalmology and Otolaryngology and the Association for Research in Ophthalmology, member of the council of the American Ophthalmological Society and formerly secretary-treasurer, attending ophthalmologist and executive surgeon to the Wills Hospital, Philadelphia consulting ophthalmologist to the Burlington County Hospital Mount Holly N J and the Jeanes Hospital, Philadelphia aged 62 died, June 5 in Philadelphia of coronary thrombosis

Juriah Harris Pierpont ☉ Pensacola Fla, Medical College of Virginia Richmond 1888 an Affiliate Fellow of the American Medical Association and member of the House of Delegates 1908-1909 three times president of the Florida Medical Association and for many years counselor of the First District past president of the Pensacola Medical Society and the Escambia County Medical Society past president of the state board of medical examiners served as a member and president of the United States pension board of medical examiners formerly health officer and city physician of Pensacola consulting surgeon to the Pensacola division of the Louisville and Nashville Railroad for many years, served as vice consul for Argentina on the staff of the Pensacola Hospital where he died, May 23, of myocarditis aged 79

William James Carroll ☉ Lieutenant Colonel U S Army, retired, Hot Springs National Park, Ark. Albany Medical College 1916 specialist certified by the American Board of Radiology Inc member of the Association of Military Surgeons of the United States Radiological Society of North America Inc and the American College of Radiology entered the medical corps of the U S Army as a first lieutenant in 1918 lieutenant colonel since 1937 retired Sept 30 1940 for disability in line of duty served during World War I aged 47 chief of the radiology section of the Army and Navy General Hospital where he died Dec 28 1942

David Edward Jones ☉ Worthington Ohio University of Louisville (Ky) School of Medicine 1928 assistant professor of medicine and director of the department of physical medicine at the Ohio State University College of Medicine Columbus formerly clinical assistant in orthopedic surgery at his alma mater served as orthopedic surgeon in charge of the poliomyelitis clinic Louisville City Hospital at one time orthopedic surgeon in charge at the Clifton Springs (N Y) Sanitarium and Clinic graduate assistant in orthopedics at the Massachusetts General Hospital Boston from 1929 to 1931 aged 42 died July 10, of cerebral hemorrhage

John Aloysius McKenna Lansdowne, Pa Medico-Chirurgical College of Philadelphia 1897 member of the Medical Society of the State of Pennsylvania at one time instructor in surgery at his alma mater veteran of the Spanish American War and World War I lieutenant colonel medical reserve

corps U S Army, not on active duty, member of the school board and board of health of Lansdowne, formerly member of the Lansdowne borough council obstetrician to the Misericordia Hospital, Philadelphia, and the Fitzgerald-Mercy Hospital, Darby aged 67 died, May 10, of arteriosclerotic cardiovascular renal disease and uremia

Anderson Watkins, Little Rock Ark, Arkansas Industrial University Medical Department, Little Rock, 1897, emeritus professor of surgery at his alma mater, now known as the University of Arkansas School of Medicine, fellow of the American College of Surgeons, past president of the Pulaski County Medical Society served during World War I, for many years city physician, member of the surgical staff of the Little Rock General and St Vincent's Infirmary, member of the staff of the Baptist State Hospital consulting surgeon to the Missouri Pacific Hospital, aged 66, died, May 26 or arteriosclerotic heart disease

Leonard Richard Ellis ☉ Hot Springs National Park Ark Vanderbilt University School of Medicine, Nashville Tenn, 1899, past president of the Garland County Medical Society, served in the Spanish-American War on the Mexican Border and during World War I, at one time an officer in the Arkansas National Guard past president of the city board of health and formerly city physician division surgeon for the Missouri Pacific and Rock Island railroads aged 68, on the staff of St Joseph's Hospital, where he died, May 10, of acute myocarditis

James Alfred, Brockton Mass, Tufts College Medical School, Boston 1897, member of the Massachusetts Medical Society aged 69 died June 12, of carcinoma of the throat

James Burns Amberson, Waynesboro, Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1868, member and at one time vice president of the Medical Society of the State of Pennsylvania past president of the Franklin County Medical Society Cumberland Valley Medical Association and the Waynesboro Academy of Medicine, first chief of the medical staff of the Waynesboro Hospital, Civil War veteran, aged 98, died June 14 of arteriosclerotic heart disease and acute bronchopneumonia

Adelbert L. Anderson, Chicago Chicago Medical School, 1923 a teacher at the Roosevelt High School aged 46 died, June 9, in the Passavant Memorial Hospital of coronary thrombosis

Samuel E Beecher, Chicago Jenner Medical College, Chicago, 1906 also a dentist, aged 72 died, June 6 in the Columbus Hospital of chronic splenomyelogenous leukemia.

Leonard Franklin Bender ☉ Philadelphia, Jefferson Medical College of Philadelphia, 1919 member of the American Academy of Pediatrics chief pediatrician at the Hospital of the Protestant Episcopal Church, consulting pediatrician at the Shriners Hospital for Crippled Children and the Northeastern Hospital, aged 49 died June 8 of coronary occlusion with hypertensive cardiovascular disease

Frank Robertson Boyd ☉ New York University and Bellevue Hospital Medical College New York, 1902 aged 65 died May 17 in the Presbyterian Hospital of cerebral hemorrhage

George Mason Brandt, Seneca Falls N Y, University of Michigan Department of Medicine and Surgery, Ann Arbor 1909 member of the Medical Society of the State of New York served as a lieutenant in the medical corps of the U S Army during World War I aged 62 died, June 5, of cerebral hemorrhage

Garrison Lee Brown Euclid N Y Syracuse University College of Medicine 1878 member of the Medical Society of the State of New York past president and secretary of the Onondaga County Medical Society served as health officer of the town of Clay aged 88 died, May 27 in Saranac Lake of myocardial degeneration and nephritis

Frederick C Brooks ☉ St Louis Beaumont Hospital Medical College St Louis 1900 served during World War I member of the staffs of the Evangelical Deaconess Home and Hospital and St John's Hospital aged 73 died May 14 in St Mary's Hospital of carcinoma of the lung and rectum

Charles M Bumstead ☉ Monticello Ill University of Pennsylvania Department of Medicine Philadelphia 1898 served on the medical advisory board at Decatur during World War I and recently as chief medical examiner for the Platt County Selective Service Board member of the board of the Platt County Tuberculosis Association at one time mayor of Monticello chief of staff of the John and Mary E Kirby Hospital on the staff of the Decatur and Macon County Hospital Decatur aged 67 died May 30 of nephritis and heart disease

Daniel Ray Campbell, Rosalia, Wash., University of Minnesota College of Medicine and Surgery, Minneapolis, 1905, served during World War I, aged 67, died, May 31, in St Ignatius Hospital, Colfax, of pneumonia

Watson Emanuel Campbell ♂ Sharon, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1907, aged 61, on the staff of the Christian H. Buhl Hospital, where he died, June 5, of meningococcal meningitis

Everett B. Currier, Phillips, Maine, College of Physicians and Surgeons, Baltimore, 1893, member of the Maine Medical Association, member of the associate staff of the Franklin County Memorial Hospital, Farmington, aged 77, died, May 22, in St Petersburg, Fla., of coronary occlusion

Joseph Robert FitzGerald, Toledo, Ohio, Toledo Medical College, 1904, aged 65, served on the staff of the Mercy Hospital, where he died, May 25, of coronary thrombosis

Louis James Frederick, Joliet, Ill., Rush Medical College, Chicago, 1892, member of the Illinois State Medical Society, health commissioner of Joliet, formerly prison and county physician, on the staffs of the Silver Cross and St Joseph's hospitals, aged 72, died, May 10, of cerebral hemorrhage

Homer Elliott Frizell ♂ Vaughan, Miss., University of Nashville (Tenn.) Medical Department, 1908, local surgeon for the Illinois Central Railroad, aged 59, died, May 13, of tuberculosis

Henry Goodfriend, Boise, Idaho, Columbia University College of Physicians and Surgeons, New York, 1898, aged 67, died, May 14, of bronchopneumonia

Dudley M. Hall, Glens Falls, N. Y., University of Maryland School of Medicine, Baltimore, 1880, member of the Medical Society of the State of New York, served as health officer and as school physician, honorary member of the associate staff of the Glens Falls Hospital, aged 81, died, May 3, of myocardial degeneration

Jesse Hartman, Crete, Neb., Nebraska College of Medicine, Lincoln, 1909, aged 71, died, June 21, in the Bryan Memorial Hospital, Lincoln, of carcinoma

Alice M. Humphrey Hatch, Des Moines, State University of Iowa College of Homeopathic Medicine, Iowa City, 1895, member of the Iowa State Medical Society, aged 79, died, June 8, of diabetic gangrene

Thomas J. Hilliard, Fairfield, Ill., Physio-Medical College of Indiana, Indianapolis, 1891, member of the Illinois State Medical Society, since 1941 a member of the "Fifty Year Club" of the state medical society, past president of the Wayne County Medical Society, past president of the Fairfield Rotary Club, a director of the chamber of commerce, aged 79, died, May 16, of cerebral hemorrhage

William Kendall James, Chicago, Bennett Medical College, Chicago, 1911, member of the Illinois State Medical Society, aged 58, died, May 27, in the Englewood Hospital of chronic vascular heart disease and hypertension

Preston Jennings Jones, Oneida, Ky., University of Louisville Medical Department, 1907, member of the Kentucky State Medical Association, past president of the Clay County Medical Society, aged 62, died, May 10, in the Good Samaritan Hospital, Lexington, of pneumonia

Jane Reid Keefer, Oak Park, Ill., Woman's Medical College of Pennsylvania, Philadelphia, 1889, member of the Illinois State Medical Society, aged 80, died, May 30, of cerebral hemorrhage and arteriosclerosis

Robert Daric Kirk, Baldwyn, Miss. (licensed in Mississippi in 1882), aged 84, died, May 5, of coronary thrombosis

David Murton Knapp, Mendon, Ill., State University of Iowa College of Medicine, Iowa City, 1896, member of the Illinois State Medical Society, aged 72, honorary staff member of St Mary's Hospital, Quincy, where he died, May 5, of edema of the lungs, congestive heart disease, hypertension and sclerosis

Norman Rudolph Kretschmar, Ann Arbor, Mich., University of Michigan Medical School, Ann Arbor, 1926, specialist certified by the American Board of Obstetrics and Gynecology, Inc., associate professor of obstetrics and gynecology at his alma mater, member of the Michigan State Medical Society and the Central Association of Obstetricians and Gynecologists, fellow of the American College of Surgeons, aged 39, died, May 5, in the University Hospital of coronary occlusion

Robert Ray Lee, Sipe Springs, Texas, University of Oklahoma School of Medicine, Oklahoma City, 1933, aged 49, died, May 16, in Fort Worth of tuberculosis

Eliot Horton Luther, Westfield, Mass., Harvard Medical School, Boston, 1921, served for several years on the Harvard Infantile Commission as diagnostician and field epidemiologist, member of the Massachusetts Medical Society, aged 47, assistant superintendent of the Westfield State Sanatorium, where he died, May 2, of pulmonary tuberculosis

William H. Lycan, Charleston, Ill., Chicago Homeopathic Medical College, 1891, member of the Illinois State Medical Society, on the staff of the M. A. Montgomery Memorial Sanitarium, aged 77, died, May 19, of coronary thrombosis

William Lawrence Madden, Jersey City, N. J., University of Maryland School of Medicine, Baltimore, 1916, member of the Medical Society of New Jersey, served in the medical corps of the U. S. Army during World War I, for many years medical examiner for the bureau of communicable diseases, city department of health and the U. S. Veterans Bureau, on the staff of the Fairmount Hospital, aged 52, died, May 10, of coronary thrombosis

Thomas A. Manes, Deckerville, Mich., Trinity Medical College, Toronto, Ont., Canada, 1894, aged 72, died, May 12, of carcinoma of the stomach

Cyrus Haymond Maxwell, Morgantown, W. Va., Gross Medical College, Denver, 1898, member and past president of the West Virginia State Medical Association, past president and secretary of the Monongalia County Medical Society, aged 80, died, July 25

John Wilson Maxwell, Chillicothe, Ohio, University and Bellevue Hospital Medical College, New York, 1899 and 1900, member of the Ohio State Medical Association, past president of the Ross County Medical Society, formerly secretary of the Ross County Academy of Medicine, aged 70, died, May 16, of carcinoma of the liver

James Benjamin Franklin McMillan, Edinburg, Texas (registered in Texas under the Act of 1907), aged 85, died, April 15, of carcinoma of the face and throat

Raymond Henderson McPherron ♂ Chicago, Northwestern University Medical School, Chicago, 1921, on the staff of the Woodlawn Hospital, aged 48, died, May 23, of coronary disease

Duncan McTaggart, Naperville, Ill., Michigan College of Medicine and Surgery, Detroit, 1894, for fourteen years member of the school board of Ray, Ind., and formerly health officer, aged 85, died, May 22, of arteriosclerosis

Joseph Michalski, Newark, N. J., Georgetown University School of Medicine, Washington, D. C., 1913, served as a major in the Polish Army during World War I, on the staff of the Hospital of St. Barnabas and for Women and Children, aged 53, died, May 22, of heart disease

Frederick Coston Monks ♂ Kittanning, Pa., University Medical College of Kansas City, Mo., 1891, past president and secretary of the Armstrong County Medical Society, aged 82, died, May 23, of cardiovascular disease

Albert Everett Obermeyer ♂ Arcadia, Ill., Barnes Medical College, St. Louis, 1906, member of the Morgan county rationing board, aged 66, died, May 25, in the Passavant Memorial Hospital, Jacksonville, of carcinoma of the kidney

Reuben Stanley Raub, Easton, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1905, member of the Medical Society of the State of Pennsylvania, health officer of Easton, on the staffs of the Betts and Easton hospitals, aged 61, died, May 28, of heart disease

George Robson Renwick, Grand Rapids, Mich., Rush Medical College, Chicago, 1892, aged 85, died, May 21, of cardiovascular degeneration, prostatism and pyelonephritis

William Rothman, Great Neck, N. Y., L. R. C. P., Edinburgh, L. R. C. S., Edinburgh, and L. R. F. P. & S., Glasgow, Scotland, 1938, member of the Medical Society of the State of New York, served on the staffs of the Greenpoint and Beth Moses hospitals, Brooklyn, aged 33, died, June 21, of coronary thrombosis

Julius Albert Edward Sass ♂ Brooklyn, Long Island College Hospital, Brooklyn, 1929, instructor in the department of pediatrics at his alma mater, served on the staffs of the Israel Zion and Kingston Avenue hospitals, aged 37, died, May 31, of coronary sclerosis

Bryant Richard Selden & Sterling Ill, University of Illinois College of Medicine, Chicago, 1927, aged 46, died, May 29, of pneumonia

Julius L. Selzer, Troy N Y, McGill University Faculty of Medicine, Montreal, Que., Canada, 1923, member of the Medical Society of the State of New York for eight years jail physician, aged 46, on the staff of the Troy Hospital where he died, May 22 of coronary thrombosis

John H. Simon & St. Louis Missouri Medical College, St. Louis, 1890, at one time health commissioner of St. Louis aged 74, was found dead May 24 of a self-inflicted bullet wound

Frank Salmeron Smith & Nevada, Iowa Rush Medical College Chicago 1882, an Affiliate Fellow of the American Medical Association, physician for the Rock Island Railroad for many years, aged 89, died, May 18 of diabetes mellitus

Russell Aubrey Smith, Brewton, Ala., Medical College of Alabama, Mobile, 1900, member of the Medical Association of the State of Alabama, president of the Bank of Brewton, formerly served as mayor aged 68, died, May 25 of carcinoma of the rectum with metastasis to abdominal incision

George Hartley Sollenbarger, Corydon Iowa College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1898, member of the Iowa State Medical Society, for many years a member of the school board and city and county physician, on the staff of the Corydon Hospital, aged 72, died May 14 of coronary thrombosis

Isaac Zalman Stalberg, Atlantic City N J St. Louis College of Physicians and Surgeons 1905 at one time associated with the Indian Service served in the medical corps of the U S Army during World War I, formerly clinical assistant in cardiology at the Temple University School of Medicine, Philadelphia, aged 60 died, May 30, in Philadelphia of carcinoma of the liver

Howard Frank Steele & Claypool, Ind Indiana University School of Medicine Indianapolis, 1920 secretary of the Kosciusko County Medical Society aged 48 died May 10 in the McDonald Hospital, Warsaw, of myocarditis and uremia

Karl Johann Swenson, Portland Ore University of Pittsburgh School of Medicine, 1908, received the Croix de Guerre and the Distinguished Service Cross for service during World War I, colonel in the medical reserve corps of the U S Army not on active duty for many years on the staff of the Emanuel Hospital, aged 64, died May 14, of coronary occlusion

Theodore Fields Thompson, Lakewood N J, University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore, 1918, member of the Medical Society of New Jersey, served during World War I, for several years school physician, on the staff of the Paul Kimball Hospital, aged 53 died, May 23, of thrombosis of the popliteal artery arteriosclerosis and coronary sclerosis

Rollin Lester Thorp Denver Bennett College of Eclectic Medicine and Surgery, Chicago 1889 Gross Medical College, Denver, 1895, member of the Colorado State Medical Society formerly a member of the city school board a member of the emeritus staff of St. Anthony's Hospital aged 82, died, May 27, of cerebral thrombosis

Walter Thomas Van Dament, Bloomington Ind Indiana University School of Medicine, Indianapolis 1912 member of the Indiana State Medical Association served in France during World War I aged 56 died May 19 of carcinoma of the mediastinum with metastasis to the bones

Evon Walker & Ottumwa Iowa State University of Iowa College of Medicine Iowa City 1905 College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1908 past president secretary and treasurer of the Wapello County Medical Society member of the staffs of St. Joseph and Ottumwa hospitals a director of the Farmers and Merchants Bank aged 66 died May 17 of coronary disease

Meyer Wigdor, Miami Beach Fla., Cornell University Medical College New York 1923 member of the Florida Medical Association served during World War I appointed a first lieutenant in the medical reserve corps of the U S Army in 1924 and in 1935 promoted to captain which terminated in 1940 by reason of declination of appointment appointed a captain in the medical corps Army of the United States in July 1942 and was honorably discharged in February 1943 by reason of physical disqualification aged 46 died April 24

DIED WHILE IN MILITARY SERVICE

Walter Douglas Campbell, Houston, Texas University of Texas School of Medicine Galveston 1920, member of the State Medical Association of Texas, began active duty as a captain in the medical corps Army of the United States, in June 1942 a member of the medical staff of the Waco Army Flying School, aged 46, died April 11, in an airplane accident 5 miles north of Hubbard

Vasco August Fanti, Wilkes-Barre, Pa Hahnemann Medical College and Hospital of Philadelphia, 1937 member of the Medical Society of the State of Pennsylvania formerly city physician served on the staff of the Wyoming Valley Homeopathic Hospital, first lieutenant in the medical corps Army of the United States, stationed at Edgewood Arsenal Md, where he died June 1, of cerebral hemorrhage aged 34

Raynor Elmore Holmes Jr, Canon City, Colo Tulane University of Louisiana School of Medicine New Orleans 1933, member of the Colorado State Medical Society, began active duty as a captain in the medical reserve corps of the U S Army in January 1940 aged 34, died July 16 1942

Arthur La Roe, Westfield, N J, Jefferson Medical College of Philadelphia 1916, served during World War I, began active duty as a captain in the medical reserve corps of the U S Army in April 1941, a flight surgeon attached to the Station Hospital at Lowry Field, Denver, aged 51 died July 21, 1942, in an airplane accident in the Latin American area

Jerome Benedict Marciniak, Chicago, Loyola University School of Medicine Chicago 1932 member of the Illinois State Medical Society served on the staff of the South Chicago Community Hospital captain in the medical corps Army of the United States attached to the 103d Infantry 328th Medical Battalion Camp Claiborne La where he died May 18 of heart disease aged 40

Benton Burkhart Mitchell, Fountain City Tenn University of Tennessee College of Medicine Memphis, 1934 member of Tennessee State Medical Association began active duty as captain in the medical corps Army of the United States in September 1942 aged 44 died June 10, in the Station Hospital, Fort Hayes, Ohio

Michael Albert Nicolais, Trenton, N J University and Bellevue Hospital Medical College New York, 1929 served on the staffs of St. Francis and Mercer hospitals major medical reserve corps U S Army aged 38, died May 16 of pneumonia and multiple myeloma

Herbert Edward Orange & Hempstead, N Y Long Island College of Medicine, Brooklyn 1932, first lieutenant in the medical corps, Army of the United States aged 35 died May 3 in the North African area

Robert Titus Phillips, Portland Maine Tufts College Medical School Boston 1932 member of the Maine Medical Association American Rheumatism Association and the International League for the Control of Rheumatism diplomate of the National Board of Medical Examiners formerly resident at the Boston City and Robert Breck Brigham hospitals Boston appointed a captain in the medical reserve corps of the U S Army in January 1941, promoted to major while a prisoner of the Japanese aged 41 died June 11 while a prisoner at a Japanese prison camp in the Philippine Islands

Ralph Hunt Sullivan Jr, Lansing Mich University of Michigan Medical School Ann Arbor 1940 for three years connected with the 119th Field Artillery of the Michigan National Guard first lieutenant in the medical corps Army of the United States ordered to active duty in July 1942 with the medical department of the Army Air Corps aged 29 died March 27 in an airplane accident at the Tonopah Bombing and Gunnery Range in Nevada

John Martin Wallace Elmhurst N Y Long Island College of Medicine Brooklyn 1939 diplomate of the National Board of Medical Examiners formerly resident physician at the Cornell University Infirmary Ithaca began active duty as a first lieutenant in the medical corps Army of the United States in August 1942 assigned to the Thirty Second Evacuation Hospital Camp Berkeley Texas later commended a few days later was killed in an airplane accident at Camp

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

The following items are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have cooperated with the Federal Trade Commission to the extent of agreeing to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Ardine—Angela Sykes trading as Sykes Laboratories, Chicago, stipulated with the Federal Trade Commission in November 1942 to cease representing that this product is a sure contraceptive, can be relied on to prevent conception or becomes Dr. King's solution when diluted in four ounces of water. Angela Sykes further agreed to cease representing by use of the word 'laboratories' or any term of similar meaning that she maintains, operates or controls a laboratory in connection with the preparation and sale of this product.

Benederm—In November 1942 Benederm Inc. which puts out this product, and Fred W. Fox the advertising agent both of Los Angeles, stipulated with the Federal Trade Commission that they would cease representing that this product is healing or is a remedy or effective treatment for skin eruptions that it renders normally present fatty detritus of the skin soluble or facilitates removal of the contained carbon particles.

Blu Tabs—The Reese Chemical Company, Cleveland which puts out this product, stipulated with the Federal Trade Commission in December 1942 that it would discontinue any advertisements which failed clearly to reveal that frequent or continued use of this product may cause nervousness, restlessness or sleeplessness that except on competent medical advice, it should not be taken by persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble, that it should not be used in case of lung disease or chronic cough and that if a skin rash appears the use of the nostrum should be discontinued. It was provided, however, that such advertisement need only contain the statement "Caution Use only as directed, if the directions for use contain a caution or warning to the same effect."

Brater's Powder and Brater's Asnarettes—These are put out by John K. Brater and Company Inc., of New York. In November 1942 that concern stipulated with the Federal Trade Commission to discontinue the following misrepresentations: that its products are beneficial for the underlying causes of asthma or are a remedy or cure for that condition, that their use will result in a quiet night or free the victim from torturous breathing, and also benefit many forms of hay fever. The company further agreed to discontinue any advertisements which failed to reveal that the frequent or continued use of the preparations should be avoided, especially by elderly persons and should be discontinued if dryness of the throat, excessively rapid pulse or blurring of the vision appear. It was provided, however, that such advertisements need only contain the statement "Caution Use only as directed" if the directions for use bear a warning to the same effect.

Curadall—In November 1942 one G. A. Labrador, Honolulu T. H., entered into a stipulation with the Federal Trade Commission to the effect that he would cease representing that this product will relieve or cure all types of skin diseases and benefit those which occur among sugar cane and pineapple workers, or that it has any therapeutic value in excess of relieving minor skin irritations.

Fetherfluff Quilts and Pads—These are sold by one Louis Katz trading as the Sanitary Feather Works, Fort Worth, Texas, whose advertising had represented that the articles in question will cause the user to enjoy a more healthful and revitalizing sleep than competing products would, that use of his commodities offers an effective treatment for rheumatism, arthritis and similar disorders or that his quilts and pads retain their efficacy without impairment for ten years and further that competing products will be harmful to the user. In a stipulation that Katz signed with the Federal Trade Commission in November 1942 he agreed to discontinue these misrepresentations.

Flurene Nose and Throat Drops and Flurene Salve—One Stephen Gardner, trading as Flurene Chemicals Ltd., Washington, N. C., entered into a stipulation with the Federal Trade Commission in November 1942 in which he agreed to discontinue the following misrepresentations in his advertising: that the nose and throat product is of benefit in relieving the nasal swelling of asthma, assisting sinus drainage or preventing hay fever, headaches or colds or that Flurene Salve loosens phlegm or helps break up congestion of the upper respiratory passage. Gardner further agreed to discontinue any advertisements which failed to reveal that his nose and throat drops should not be used in excessive amounts or given to infants and younger children except on competent advice, and that persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble should not use the preparation except on competent

advice. It was provided, however, that if the label carried a warning to the same effect, it would be sufficient for the advertisements to state "Caution Use only as directed."

Koto Cleansing Cream, Koto Vanishing Cream and Koto Lemon Almond Lotion—These are put out by a William Banks, trading as Koto Cosmetic Company, Pittsburgh. In November 1942 Banks signed a stipulation with the Federal Trade Commission, agreeing to cease representing that any of these products is of value for skin troubles or effective in preventing or curing blackheads, pimples, freckles or wrinkles. He agreed further to discontinue representations that "Koto Cleansing Cream" is free from wax or will penetrate the pores that "Koto Lemon Almond Lotion" will whiten the skin or has been tested or approved by a chemist, or that he employs a chemist and "beautician" when such is not the fact.

Liquid Chin Strap—This is put out by Delettrez, Inc., Long Island City, N. Y. In October 1942 the concern entered into a stipulation with the Federal Trade Commission, agreeing to cease and desist from representing that its product will help ward off the appearance of age or grayish surface lines, heighten the arch or sweep of chin lines, benefit the skin or contour thereof, or produce any physiological effect other than a temporary feeling of an astringent at the site of its application, or that the use of it will result in even temporary disappearance of crepey skin.

Man O Reo—Charles P. Mouroe trading as Man O Reo Products, Greensboro, N. C., markets this product. In October 1942 he stipulated with the Federal Trade Commission that he would no longer represent that his product is an aid to digestion will rid the system of poisons or gases, can be relied on to relieve gastric disturbances, heartburn, stomach disorders, nervousness and insomnia, possesses the rebuilding qualities of a tonic and is incapable of having any deleterious effect on the digestive organs. He further stipulated that he would discontinue any advertisement which failed to reveal that "Man O Reo" should not be used when abdominal pains, nausea or other symptoms of appendicitis are present and that its frequent or continued use may result in dependence on laxatives. It was provided, however, that it would be sufficient to include in the advertising only the statement "Caution Use only as directed" if the directions for use in or on the trade package contained warnings to the same effect.

Padol Machineless Permanent Wave, Lifeoil Machine Permanent Wave and Dio Dane No. 100 (shampoo)—These are distributed by Bonat and Bonat, Inc., New York, which concern in December 1942 stipulated with the Federal Trade Commission to cease representing that the first named product nourishes the hair or gives it a deeper wave, that the second named contains lanolin or that the shampoo nourishes the hair and is not a soap.

Posturite and Ortho Flex Mattresses—The advertisements of these represented that they are of such construction, scientific or otherwise as to insure correct posture during sleep that insomnia and other serious disorders are caused by faulty mattresses that the latter interfere with the functioning of the sleeper's organs and that healthful sleep is not possible on a soft mattress. In December 1942 the Burton Dixie Corporation Chicago which sells the above named mattresses stipulated with the Federal Trade Commission to discontinue such misrepresentations. The corporation further agreed to cease using the term "Ultra Violet Ray Processed," either alone or in connection with the word "vitahized" or any other term of similar implication, as descriptive of its products the effect of which might give the impression that the products have been completely sterilized or endowed with health giving qualities which they do not possess. Further, the concern agreed to cease using on its products any labels on which appear the terms "doctor" or "Dr.," either alone or in connection with a name to imply that the products so labeled are made in accordance with the design or under the supervision of a doctor of medicine or contain special or scientific features resulting from medical determination or services.

Vanola Laxative Herb Tea—This is put out by Wladyslaw Ochrymowicz and Theodosia Wandycz Ochrymowicz, trading as Vanola Herb Tea Company, New York. A stipulation was signed in November 1942 with the Federal Trade Commission by these persons, in which they agreed to discontinue the following misrepresentations: that their product is an adequate treatment or effective remedy for stomach disorders, headache, dizziness or digestive disturbances or has any value except as a temporary laxative for the relief of constipation that the condition known as sour stomach is caused by temporary constipation and is benefited by the product in question, that this preparation can be relied on to make the user healthier or has any effect in inducing sound sleep. The respondents further agreed to discontinue any advertisement which represented that this tea is safe or which failed to reveal the potential danger in its use when nausea, vomiting or other symptoms of appendicitis are present provided, however, that if the directions for its use wherever they appear in the labeling, contain an adequate warning of its potential danger to health as aforesaid the advertisement need only contain the cautionary statement "Caution Use only as directed."

Zdroj—This is promoted by the Gramercy Chemical Company Inc. and an Andrew Borak, both trading as the Roxola Company Brooklyn. In December 1942 they entered into a stipulation with the Federal Trade Commission agreeing to cease representing that this nostrum is recommended by doctors for digestion or that it has any favorable influence on the digestive processes, that it is a competent treatment for debility of the stomach or liver that it stimulates the secretory glands of the body or is of any benefit except as a temporary laxative for the relief of constipation. Further, the promoters agreed to discontinue any advertisements which represented that this product is safe to use or which failed to reveal the potential danger in its use in the presence of nausea, vomiting or other symptoms of appendicitis provided however that in the directions for use wherever they appear contain an adequate warning of its potential danger to health although the advertisements need only contain the cautionary statement "Use only as directed."

Correspondence

BROMIDISM AFTER EXCESSIVE DOSAGE OF PROSTIGMINE BROMIDE

To the Editor—In the June 19 issue of THE JOURNAL Dr J M Nielsen reports a case of bromidism attributed to excessive use of prostigmine bromide in myasthenia gravis. The author of the report is, as he states, aware of the fact that the amount of bromide taken was small but that even with the small dose such an accumulation resulted that a blood concentration of 225 mg per hundred cubic centimeters was eventually reached. The author explains this remarkable accumulation on the ground that for any dosage of bromide the concentration in the blood shows enormous individual variations.

On the contrary it has been thoroughly demonstrated that the accumulation of bromide depends on definite physical characteristics and physiologic functions—dosage in relation to body weight, volume of extracellular fluid and rate of excretion of sodium chloride. The accumulation shows no greater individual variations than those of these characteristics and functions. Prostigmine bromide contains only about a third as much bromide by weight as does sodium bromide. The maximum dose of prostigmine bromide taken by the patient who was the subject of the report was 240 mg in twenty-four hours; this would correspond to less than 83 mg, about $1\frac{1}{3}$ grains, of sodium bromide a day. Under no circumstances could a patient so accumulate bromide on this dose as to reach a concentration in the blood of 225 mg per hundred cubic centimeters or one even approaching it.

The weight of the patient is not stated but, if we assume 50 kg and an extracellular fluid of 20 per cent, the actual weight of sodium bromide present in the body to give a concentration of 225 mg per hundred cubic centimeters would be of the order of 22 or 23 Gm. Bromide during administration is continuously excreted in the urine. But even ignoring all excretion it does not appear in the case reported that for the full time of administration this amount of bromide as prostigmine bromide, was administered. It seems improbable that prostigmine bromide can cause an accumulation of more bromide than is given.

In at least some of the clinical reports in the literature in which high concentrations of bromide in the blood are said to follow from low intake there is grave doubt as to whether the physician made a sufficiently careful examination to exclude the possibility of bromide being taken surreptitiously but has accepted only the statements of the patient and relatives that none was taken. In the present instance the assumption was apparently made only on this basis. Furthermore, in many cases diagnosed as bromidism the underlying difficulty is not primarily bromide but the psychopathic or psychotic state for which the bromide was taken. The finding of bromide in the blood even in small amounts gives a convenient direction to the diagnosis which without this finding would be made as some other state. Consequently the belief is held as stated by the author of the case report that the individual variations in response to any concentration of bromide in the blood are enormous. In the present instance there was sufficient bromide in the blood to cause symptoms. The difficulty here is that the patient did not receive enough bromide as prostigmine bromide to account for the concentration.

It is suggested here that the author was perhaps too easily convinced by the statement of the husband that there was no medication for the patient's anxious and fearful states except an occasional dose of phenobarbital.

Clinical reports of this sort become a part of the scientific literature and are used as a basis for evaluating the action of drugs—in this instance bromide—quite as much as are the results of carefully controlled laboratory investigations. Because of their important place in the literature, such reports, especially when dealing with the dosages of drugs, should be made only with the same safeguards as those expected for reports of laboratory investigations. The author may have applied such safeguards but the evidence presented does not show it.

EMERGENCY FURLOUGHS

To the Editor—In Mr Bondy's absence from the city I am writing concerning the procedure to obtain an emergency furlough for a serviceman stationed outside the continental United States.

Permission for an emergency furlough may be granted only by the man's commanding officer and the military and naval authorities are placing more restrictions on the granting of furloughs. Arrangements for furloughs are rendered increasingly difficult because of the problems of locating a serviceman and limited facilities for communication and transportation. Many men are stationed where the distance involved practically precludes a furlough being granted. Servicemen may be ready to embark for foreign stations or be en route under sealed orders in which instances they may not be reached. It is frequently impossible to reach naval personnel immediately if they are attached to ships.

Military and naval authorities frequently ask for full details. In cases of illness a doctor's diagnosis and prognosis and a doctor's statement of the need for the serviceman's presence should be quoted. The serviceman initiates a request for a furlough to his commanding officer who may grant it at once or may ask the Red Cross field director at the army post or navy station to secure further information through the serviceman's home Red Cross chapter. The chapter Home Service worker on receipt of this request verifies illnesses, other conditions, meets any emergency needs of the family and telegraphs the field director a statement of the circumstances. The chapter neither recommends nor approves a furlough but states the facts including recommendations of the doctor or other responsible persons.

The practice of relatives initiating the request for an emergency furlough and the Home Service worker or the chapter immediately verifying the circumstances to the field director has been endorsed by many commanding officers as a means of expediting the granting of the furlough.

If a member of a serviceman's family makes the initial request to the local Red Cross chapter he should be advised to notify the serviceman immediately of the situation and at the same time the chapter Home Service worker should inquire into the situation and immediately telegraph a full statement of facts to the Red Cross field director serving the station where the man is located. It is desirable that two telegrams be sent one to the serviceman from his family and one from the local Red Cross chapter to the field director. Families may send telegrams of their own to many places outside the United States through the facilities of the commercial cable companies. Where there are no commercial facilities available the chapter Home Service worker will telegraph Home Service American National Red Cross Washington D.C., asking consideration of the emergency request and stating that no commercial cable facilities are

available. The message will then be relayed by cable or radio to the Red Cross field director at the man's post.

It seemed desirable to give a full statement so that your readers may be apprised of the factors involved. We believe that it will be helpful to publish this information in *THE JOURNAL*.

DOV C SMITH, Washington, D C
Deputy Administrator, Services to the Armed Forces

"THE PHENOMENON OF BLACK DERMOGRAPHISM"

To the Editor—In the article on "The Phenomenon of 'Black Dermographism'" by Urbich and Pillsbury (*THE JOURNAL*, February 13, p. 485) the authors state that the phenomenon was first reported by Lindin and Kusmenko in 1925, but in the discussion Anderson and Becket cited studies made on this subject sixty years ago.

The following references may also be of interest.

In 1902 Solomon Solis-Cohen (A Further Contribution to the Subject of Vasomotor Ataxia, *Tr Assn Am Physicians* 17:644, 1902) stated: "In certain patients, especially those with more or less constant red flushing of the face, if a silver probe be drawn across the flushed cheek a bluish black mark will be left, which can afterward be wiped off. I assume that this is due to the formation of silver sulphide, but I have not as yet been able to have a chemical study made."

Ten years later he wrote (Brief Notes on Vasomotor Ataxia, *M Rev of Rev* 18:21 [Jan] 1912): "Silver, less frequently gold, copper, nickel, leaves a bluish black or brown mark when drawn over the skin of face or breast. Black mark due to talc or zinc oxide face powder must be excluded." This phenomenon was given by Leon Solis-Cohen in 1917 among the Chief Tests of Autonomic Ataxia (Sympathetic Nervous System, Reference Handbook of the Medical Sciences, ed. 3, New York, William Wood & Co. 8:61, 1917).

A black line appeared when silver was drawn across the face in 40 per cent of 119 tuberculous patients whom I tested in 1917 (A Study of the Signs and Symptoms of Autonomic Disturbance Occurring in Pulmonary Tuberculosis, *Am Rev Tuberc* 1:289 [July] 1917).

MYER SOLIS-COHEN, M D, Philadelphia

TETANUS IMMUNIZATION

To the Editor—In *THE JOURNAL*, June 19, page 559, Dr. Geoffrey Edsall, Boston, stated that "in the American army the official procedure (Circular Letter 34, S G O [4/16/41], Long, A P. Tetanus Toxoid. Its Use in the United States Army, *Am J Pub Health* 33:53 [Jan] 1943) is to give two initial doses of fluid toxoid three weeks apart, a stimulating dose one year later or on departure for a theater of operations."

I believe there is a slight error, probably typographic, as this particular circular of the Surgeon General, United States Army, states that the initial vaccination consists of three subcutaneous injections of tetanus toxoid (plain) of 1 cc each, administered with intervals of not less than three or more than four weeks, and preferably with intervals of three weeks between doses. There are, however, some students of immunology who recommend a much longer period, up to six months, between the second and third injections, to obtain a more lasting immunity.

CONTINUOUS CAUDAL ANESTHESIA

To the Editor—In the July 3 issue of *THE JOURNAL* Dr. Maurice Small of Parsons, W. Va., wrote a clinical note with the title "A Serious Complication of Caudal Anesthesia." In his note he states that while one of his patients was getting caudal anesthesia she went into respiratory failure and resuscitatory measures had to be instituted in order to save her life.

As a worker in the field of caudal anesthesia, I would like to make some comment on this case. There is no doubt that the needle was in the caudal space, as was proved in two ways: 1. The rate of flow of the gravity drip was 60 drops per minute. 2. The patient had good anesthesia and analgesia and had been getting the injection for a full hour before untoward symptoms appeared. If the needle had been in the spinal canal the patient would have made her exitus long before an hour had elapsed, since procaine or nitycaine diffuses very rapidly through the spinal fluid. The fault, therefore, in this near catastrophe was not the site of injection but rather allowing the level of anesthesia to ascend too high.

In the method as devised at Sinai Hospital, we allow saline solution to drip in once the needle is in the caudal space, and if the rate is compatible with the caudal flow then procaine hydrochloride 1 per cent is allowed to drip in at 60 drops per minute until anesthesia is obtained to the level of the tenth thoracic vertebra or the umbilicus. When this level is obtained, the drip is cut down to 12 to 15 drops per minute, which is a maintenance dose. Of course, this maintenance dose will vary from patient to patient according to their ability to metabolize procaine.

If we review the anatomy of the uterus and its innervation, we find that the somatic innervation of the uterus comes from the tenth, eleventh and twelfth thoracic and part of the first lumbar vertebrae, so that the level of anesthesia required for the relief of uterine pains is about the level of the tenth thoracic vertebra or the umbilicus. The level or height of anesthesia depends on two factors: the rapidity of the injection and the amount of procaine hydrochloride injected. If we want higher levels of anesthesia, we can obtain it by allowing procaine to run in at the original drip, which may vary from 40 to 150 drops per minute. The procaine dissects up the extradural space higher and higher until the intercostal nerves and finally the third, fourth and fifth cervical nerves are anesthetized and the patient goes into respiratory failure. This is what happened in Dr. Small's case. By allowing the drip to run at its original rate and not testing the patient for the proper level, the nitycaine which he used dissected itself up extradurally until the patient went into respiratory paralysis.

In giving caudal anesthesia for labor and delivery, it is very important that, once anesthesia is obtained, the proper level should be maintained and not allowed to rise any higher. Dr. Small's case was in reality not a complication but rather an error in maintaining the proper level.

In closing I wish to stress two important facts:

1. The most important point in the giving of caudal anesthesia is to be sure that the caudal needle is in the proper space and not in the subarachnoid space. This can be ascertained by simply allowing isotonic solution of sodium chloride to run into the caudal space as explained in the previous article.

2. Once the proper level of anesthesia is obtained, the drip must be cut down and only a maintenance dose allowed to run in. The maintenance dose required will vary from patient to patient and on the whole will probably be 10 to 15 drops per minute.

Council on Medical Education and Hospitals

COURSES FOR GRADUATES AT HARVARD MEDICAL SCHOOL

Harvard Medical School has informed the Council on Medical Education and Hospitals that the following continuation courses for practicing physicians published in the July 3 issue of THE JOURNAL have been canceled for the duration of the war

Anatomy—Microscopic Anatomy July August six weeks

Medicine—General Course in Internal Medicine August 1 four months A one month course in Internal Medicine will be given for the month of October 1943 Fee \$150 Otherwise all courses in Internal Medicine have been canceled for the duration of the war

Internal Medicine September 1 September 15 one year All of the one year courses in Internal Medicine have been canceled for the duration of the war

Selected Subjects in Endocrinology and Metabolism August two weeks Military Medicine—Military Medicine and Surgery to be announced two weeks

Otolaryngology—Bronchoscopy and Esophagoscopy Arranged two weeks full time

Pathology—With the exception of the course Pathology of Obstetrics and Gynecology which is still available all the courses in pathology have been canceled for the duration of the war

Pediatrics—The one year course in Pediatrics has been canceled for the duration of the war

Psychiatry and Neurology—All postgraduate courses in these departments have been canceled for the duration of the war

Surgery—The courses in Endoscopy and Minor Surgery have been canceled for the duration of the war

A new two week course in Pediatrics is to be given at Harvard Medical School August 2 to 14 inclusive at a fee of \$75

The one month course in General Roentgenology listed in the July 3 issue of THE JOURNAL with a fee of \$50 is a part time rather than a full time course

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Abandonment of Patient Actionable Only When Injury Results—The plaintiff scratched the tip of his right thumb in February 1936 without drawing blood. Several days later the thumb hurt and he pierced it with a sterilized needle causing a bloodlike liquid to flow. He repeated the procedure a few days later. The pain in the thumb became more severe and on March 10 the plaintiff visited the defendant physician who diagnosed the infection in the thumb as a felon. He incised the tip to drain pus and found that a portion of the bone and tissue in the tip was necrotic. The physician directed the patient to keep the thumb in a hot epsom salt or boric acid solution. The following day the physician dressed the wound renewing the instructions previously given. The patient visited the physician daily until March 16 when after a roentgenogram had indicated that there had been no restoration of circulation in the necrotic portion of the thumb the physician removed a small piece of the distal phalanx. The next day the wound was again dressed. On the 18th the thumb was very painful red streaks appeared in the forearm from the wrist about halfway to the elbow the patient had a temperature of 99.2 F and a small lump appeared in the patient's arm. On the 19th the patient again visited the physician but the red streaks had subsided and the patient's temperature was normal. Starting that afternoon however the hand became ever more painful and the patient tried unsuccessfully for five days to reach the physician by telephone. When the physician was reached on the phone about 10 p. m. he reached according to the patient's wife to visit the patient on a certain day the patient was unemployed and that he would be unable to pay them any further and suggested that the patient be sent to the county hospital. According to the physician the patient

advised the wife that hospitalization was imperative and on learning that the patient was unemployed promised to arrange for admittance to the county hospital but informed her that on admittance he could no longer treat the patient. In any event, the physician's connection with the case terminated at that time. Another physician, Dr Foster, was called and reached the patient about 10:20 p. m. He administered a hypodermic and had the patient removed to a private hospital. The next morning Dr Foster called in Dr Allen, a surgeon, to take charge of the case, and on March 22 Dr Allen operated on the hand. Between that date and May 4, when the patient was removed to another hospital, Dr Allen made numerous incisions in the hand in an effort to establish drainage and prevent the infection from spreading. Shortly after May 4 an amputation—just how extensive is not made clear—was performed. Three additional amputations were performed, the last one being performed on Jan 11, 1937, when the arm was amputated at a point $5\frac{1}{4}$ inches from the armpit. Subsequently action for malpractice was instituted against the defendant physician, and the jury returned a verdict in favor of the patient. The trial court, however, believing that it had erroneously instructed the jury, ordered a new trial, and the plaintiff appealed to the Supreme Court of Washington.

The instruction that the trial court concluded was erroneous told the jury that if it found that the physician was negligent and unskillful in the treatment of the patient's infected thumb by withdrawing from the case while the infection was active and dangerous, and that such negligence on the physician's part proximately caused resulting damage to the patient, then the jury should return a verdict in favor of the patient. This instruction, said the court, permitted the jury to consider, as an element for which they might award the patient damages, the act of the physician in withdrawing from the case on the evening of March 19. This instruction was erroneous because there was no evidence in the record to indicate that any injury resulted to the patient by reason of the alleged withdrawal. Whatever injury may have subsequently resulted to the patient bore no causal relation to the allegedly improper withdrawal by the defendant physician. It must be remembered that Dr Foster visited the patient about twenty minutes after the defendant allegedly terminated his connection with the case and that he then took charge of the case and moved the patient immediately to a hospital and called in Dr Allen the next morning to take charge of the case. It is the general rule, continued the court, that when a physician undertakes to treat a patient it is his duty to continue to devote his best attention to the case until either (1) medical care is no longer needed, (2) he is discharged by the patient or (3) he has given the patient reasonable notice of his intention to cease to treat the patient so that another physician may be obtained. Abandonment of a case by a physician without sufficient notice or adequate excuse is a dereliction of duty, and if injury results therefrom the physician may be held liable in damages. Under the evidence the jury might have found that the physician had abandoned the patient without sufficient justification, and if the record contained sufficient evidence that would support a finding that by this abandonment the patient suffered injury, doubtless the instruction as given was correct. It is not, however, sufficient that the patient introduce evidence showing merely the breach of some duty by the physician, the patient must go further and show that such breach of duty resulted in some compensable injury to the patient. In this connection, the only evidence relied on by the patient is that of a physician called as a witness by the patient. He stated that the defendant physician was negligent in his treatment and that he failed to incise the infected area properly and to take necessary tests to aid him in determining the proper course of treatment, but this witness did not testify, nor is it a reasonable inference from this testimony, that the patient suffered any damage or that his condition became worse because the defendant physician terminated his care and treatment of the patient, leaving him without a physician or medical assistance for perhaps half an hour on the evening of March 19. The record contained no evidence that there was any causal connection between the situation referred to and the later suffering endured by the patient or the creation of the condition which resulted in the amputation of the patient's

arm. The basic question to be determined is one of causation. It does not appear that had the defendant physician responded to the telephone call as soon as he received it on the evening of March 19 he could have reached the patient any sooner than Dr Foster did. All the physicians who testified agreed in the opinion that from the time the red lines first appeared on the patient's arm, March 18, there was every indication that the patient was suffering from lymphangitis. We find no evidence, said the court, on which could be based a judgment for damages in the patient's favor occasioned by the physician's refusal to visit the patient on the evening of March 19.

The patient argued that the mental suffering endured by him because of his abandonment by the physician would support a verdict for judgment in his favor. It was intimated, too, that there was evidence of actual physical injury to the patient because of the defendant's failure to act on the evening in question. The patient, said the court, was not acquainted with any other physician in this particular city. He knew that his thumb and hand had become progressively worse and that while the defendant had refused to attend him he had told him that he was in need of hospitalization. Conceding that the patient might well be disappointed and mentally perturbed because of the physician's refusal to visit him, such a mental condition is not sufficient alone to support an award. In connection with this phase of the argument, the patient cited *Ricks v Budge*, 91 Utah 307, 64 P (2d) 208. In that case the plaintiff was suffering from an infected finger which had been incised by the defendant physician in that case to establish drainage. The plaintiff's condition having become worse, the physician indicated that a further operation was necessary and that the plaintiff should go to a hospital. The plaintiff then went to a hospital conducted by the defendant physician and was being prepared for the operation when the physician refused to continue to treat the plaintiff because of an old unpaid account which the physician discovered the plaintiff owed him. The plaintiff then dressed, left the hospital in the rain and walked to another hospital, where an operation was performed on his hand. The court in that case held that the plaintiff's case should be submitted to the jury, the court being of the opinion that it could not be held as a matter of law that the plaintiff had suffered no damage from the abandonment. That case, however, said the Supreme Court of Washington, is not controlling here, as it appeared that the physician admitted that at the time of his abandonment of the plaintiff in that case the patient was in a dangerous condition and in dire need of immediate attention. In this case, after Dr Foster was retained he procured Dr Allen to take charge of the case, no radical change in the treatment of the patient's hand was made and no operation was performed thereon until March 22.

The court accordingly concluded that the trial court properly ruled that error had been committed in submitting to the jury the question of negligence on the part of the physician and resulting damage to the patient based solely on the physician's withdrawal from the case on the evening of March 19. In effect, the Supreme Court accordingly ordered a retrial of the cause—*Gray v Davidson*, 130 P (2d) 341 (Wash, 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Primary Sciatic Neuritis—The 55 cases analyzed by Alpers and his associates were selected as authentic examples of sciatic neuritis. Thirty-seven or 67 per cent of the cases were in males all but 4 of whom were engaged in heavy work and were exposed to changes in weather. Sciatic neuritis is a disease of middle age or early old age. The diagnosis of sciatic neuritis and its differentiation from secondary sciatica is not difficult. Sciatic neuritis is always characterized by tenderness of the nerve trunks and usually also of the muscles of the thigh and calf. All other diagnostic criteria such as weakness or atrophy of leg muscles decrease or absence of the achilles reflex pain on stretching the sciatic nerve sensory disturbances and the like are as characteristic for one form of sciatica as for the other. Special signs such as Lasègue's and Verri's all of which depend on the stretching of the sciatic nerve are also characteristic of both groups. Feeling divided the sciaticas into primary or essential sciatica and secondary or symptomatic sciatica. This classification serves all practical purpose is accurate and emphasizes the fact that sciatica is

produced by many causes. The cases of sciatic neuritis must be considered quite apart from those of other origin. The fact that no cause can be established for such cases does not justify their classification as idiopathic.

Familial Mediterranean Target-Oval Cell Syndromes

—Dameshek reported in 1940 the case of a young man of Italian origin who presented a moderately severe hypochromic anemia with numerous target cells definite splenomegaly moderate hemolytic icterus and generalized osteoporotic changes commonly seen in Cooley's erythroblastic anemia. He suggested that the fundamental fault in Cooley's anemia might center about the target cell, which might be the inherited defective factor. The present study concerns 10 Italian families and 1 Italian bachelor comprising all together more than 50 individuals all affected with what is believed to be a similar condition but one of varying degrees of intensity. In addition blood smears of 60 consecutive persons of Italian origin were examined for oval target and stippled red cells. Dameshek shows that it is possible to arrange in a descending scale beginning with the rare Cooley's anemia various more frequent hereditary syndromes which present as a common denominator a reduction in the hemoglobin level hypochromia abnormalities of the red cells including the presence of target cells oval cells stippled cells increased hypotonic resistance and complete retractorness to iron therapy. At the lower end of the scale are individuals without anemia but showing increased numbers of target or oval cells. Possible relationships among the syndromes is indicated by the following: 1 Some siblings and both parents of the patients with Cooley's anemia showed the hematologic changes of mild Mediterranean target cell syndrome. 2 The various groups merged into one another. 3 Individuals of the same families occasionally showed the same variations as were noted in the groups. Cooley's anemia is probably the most severe manifestation of a hereditary disorder which occurs in people of Mediterranean origin and in which target cells and increased hypotonic resistance are prominent features. The fundamental inherited abnormality appears to lie in a disturbance of the hemoglobin metabolism which makes the nucleated red cells deficient in and unable to take on their normal complement of hemoglobin. In consequence thin and hypotonically resistant erythrocytes (target and oval cells) are produced. Basophilic stippling and retractorness to iron therapy are probably concomitant abnormalities. The increased hemolysis in the more severe cases may be due to the breakdown of unused hemoglobin precursors. There are resemblances between Mediterranean target cell syndromes and African sickle cell anemia. It is possible that the two conditions are closely related entities with unusual erythrocytic thinness (leptocytosis) as one of the fundamental traits. They are important not only diagnostically but because the mating of 2 individuals with relatively mild forms may result in the appearance in the offspring of full blown Cooley's anemia or sickle cell anemia.

Mixed Bacterial Oral Cold Vaccine—Siegel and his co-workers report the experience of the Visiting Nurse Service of New York City with bacterial vaccines in the prevention of the more usual respiratory complications. The study was limited to volunteers of the nursing and office staffs. They were divided into two groups depending on the number of colds experienced in the preceding year. Each group was further subdivided into those with (a) chronic sinusitis bronchitis or otitis (b) allergies and (c) no clinical manifestations making six classifications in all. A commercial product composed of mixed heat-killed bacteria (about 25 billion pneumococci 15 billion streptococci 5 billion Hemophilus influenzae and 5 billion Micrococcus catarrhalis per dose) was prepared in the form of capsules to be taken orally. The control group was given capsules identical in appearance and containing the same ingredients without bacteria. The evidence indicates that the oral administration of a commercially prepared vaccine or mixed killed bacteria failed to decrease the incidence of acute respiratory infections to reduce the severity or duration of such infections and to prevent secondary bacterial complications. Both control and inoculated groups had the same number of colds and there was no significant difference in the duration of symptoms and the number and variety of medications following the cold. These observations seem to be made by

various investigators that, contrary to fairly widespread medical and lay opinion, the so-called cold vaccines are of questionable value as a prophylactic measure against the common cold and its bacterial complications.

Sulfamerizine in Man—Murphy and his co-workers present observations on the absorption, distribution and excretion of sulfamerizine in human beings. To one group of persons a single dose of the drug was administered orally, subcutaneously, intravenously or rectally, while multiple doses were administered over a period of days to another group. Studies were made on the behavior of sulfamerizine in 28 convalescent patients serving as controls and on 20 patients with acute bacterial infection. The data presented indicate that after a single 3 Gm oral dose of sulfamerizine higher blood serum levels are attained more rapidly and sustained longer than after similar amounts of sulfadiazine. Desired serum concentrations can be obtained by giving sulfamerizine sodium subcutaneously or intravenously. Sulfamerizine is readily diffused through body fluids and enters the red cell in varying concentrations. Sulfamerizine is slowly excreted in the urine in amounts roughly comparable to sulfadiazine.

Iliac Lymphadenectomy in Cancer of Cervix—Taussig points out that radiation therapy usually fails to destroy cancer metastases in the tributary lymph nodes. Removal of these nodes was for years considered an essential feature of the radical Wertheim hysterectomy. The high operative mortality of this extensive procedure led many to abandon it. The procedure is applicable in a relatively small number of group I (League of Nations Classification) cancers of the cervix. Group II cases in which there is involvement of the parametrium or upper third of the vagina without extension to the pelvic wall are two to three times as numerous as the group I cases. Taussig attempted to obtain better results for this group by combining lymphadenectomy with irradiation of the primary tumor. Leveuf in France and the author here have independently conceived the possibility of this method of attack. Leveuf carried out this procedure in only a few cases, while the author employed it in 175 group II cancers of the cervix. The operative mortality in this group was 17 per cent with a mortality of 07 per cent in the last 140 cases. The five year survival rate of 70 patients operated on previous to October 1937 was 386 per cent. Comparing this with a five year survival of 229 per cent in 118 similar cases treated with radiation alone, there was a 68 per cent greater salvage when the lymph node removal was added to the radiation treatment. Cancer was found present in the lymph nodes in 268 per cent of the 175 patients operated on. A five year salvage of 21 per cent was obtained even in cases with demonstrated metastases. Lymph node dissection appears to be a valuable adjunct in the treatment of group II cancers of the cervix.

Rh Factor and Erythroblastosis Fetalis in Chinese—Recent studies have revealed, Levine and Wong point out, that isoimmunization of the Rh—mother by the dominant Rh factor of fetal blood is the essential feature in the pathogenesis of at least 90 per cent of the cases of erythroblastosis fetalis. The intrauterine hemolysis of the fetal blood, which is respon-

sible for erythroblastosis fetalis, is due to the action of maternal immune anti Rh agglutinins on the susceptible Rh+ fetal blood. The incidence of the Rh factor is different in the white and the colored races. With a particular human anti Rh serum there are 15 per cent Rh—white individuals in contrast to values varying from 5 to 8 per cent among the colored persons. Clinical observations indicate that the incidence of erythroblastosis fetalis was 21 per cent for the white and 07 per cent for the colored races. Wong expressed the opinion that this condition is probably rare among Chinese infants. If this could be shown to be correct, one should expect to find a low incidence of Rh—individuals in a random Chinese population. This was confirmed in a study of 150 Chinese persons residing in New York City, only one of whom was Rh—. Using the anti Rh serum, which may be considered as standard, Rh—persons are twenty-one times less frequent among the Chinese than among the white persons. This observation supports the contention that erythroblastosis fetalis is rare among Chinese infants.

Management of Tumors of Breast—Robillard and his associates report 351 cases of carcinoma of the breast treated since 1935 at the Brooklyn Cancer Institute. The Steintal classification has been adopted by the authors. Radical mastectomy is the procedure of choice. Five year survivals vary from 30 to 40 per cent without evidence that such differences are due to specific modes of therapy. The fact most profoundly influencing the number of five year arrests is apparently the percentage of early or Steintal I cases. Improvement over the 30 per cent five year survival rate reported forty years ago after radical mastectomy alone has not been biometrically established. The essential determinants then as now appear to be the rate of preoperative growth and the tendency to localization or metastasis. The five year survival rate for untreated cases is about 20 per cent. All these survivors have active lesions. After radical amputation roughly one third of the patients survive. Thirty to 40 per cent are aided by present methods of treatment. Sixty to 70 per cent are doomed to failure. The baffling intrinsic factors predicate failure in some two thirds of all cases. In the 30 per cent which are benefited the percentage of Steintal I and the radical mastectomy are the major factors for success.

Sulfathiazole in Venereal Disease Prophylaxis—Arthur and Dermom studied in a unit of Negro troops a series of 586 known exposures to contacts almost certain to be infected with venereal disease. Sulfathiazole prophylaxis was instituted

the morning after exposure. It consisted of 3 Gm after breakfast 2 Gm after dinner and 1 Gm after supper. The drug was administered to 152 men, of whom 40 repeated this prophylaxis one or more times after subsequent exposures. Of 384 exposures in 259 men not followed with sulfathiazole, 42 resulted in infection of which 9 were primary syphilis. After 199 exposures in 152 men followed by sulfathiazole prophylaxis 1 developed a chancre and 5 syphilis. One of these was a secondary syphilid and the rest exhibited a positive serologic test but no signs. The rate of infection per thousand exposures to venereal disease for those not taking sulfathiazole after contact was 109 for those who received sulfathiazole the rate of infection was 30 per thousand exposures. The authors conclude that sulfathiazole is a valuable adjunct to the routine army prophylaxis against venereal disease. It also seems to be of value when used alone. It is suggested that it be given when routine prophylaxis has been omitted. Sulfathiazole prophylaxis may interfere with the development of the macroscopic chancre or syphilis.

Agranulocytosis Following Quinine—Franks and Davis report the treatment of a soldier aged 26 with quartan malarial blood for cerebrospinal syphilis. Induced malaria was terminated following the second paroxysm of fever. Five grains (0.3 Gm) of quinine sulfate was given three times daily. Twenty-four hours after the first dose of quinine a leukopenia was noted. Five days later the patient complained of a sore throat. The tonsils and pharynx became distinctly injected and mildly ulcerated. The gums were sore and red. Palpable tender lymph nodes were noted in the cervical and submaxillary regions. Daily intramuscular liver therapy was initiated. All other medication except quinine was discontinued. The leukocyte count was now 2000 the segmented cells were disappearing and the lymphocytes rose to 97 per cent. Thirty cc of pentnucleotide given every other day caused a rise in the total leukocyte count but no increase in the number of granulocytes. Leukopenia and agranulocytosis continued unchanged. At this stage quinine was discontinued and the leukocyte count immediately increased with an accompanying rise in the segmented cells. The authors were able to find only 4 cases in the literature in which quinine was thought to be responsible for agranulocytosis. Many observers mention the deleterious effect of the benzene ring in producing granulopenia. Quinine (oxy-methylcinchonine) has a molecular nucleus much like that of the benzene ring. It also contains the toxic NH radical in which the H is replaced by Ch which radical likewise has been thought to be responsible for the injurious effect.

Pectin Agar Feeding in Tuberculous Enterocolitis—According to Crimm and his associates the incidence of intestinal tuberculosis as a complication of pulmonary tuberculosis has been reported as low as 20 per cent and as high as 92 per cent. In the authors' experience excess of calcium and of vitamins D and C in the diet did not augment the cure. Twelve of our patients of whom 20 had far advanced and 4 had early advanced disease were placed on a growth or "bacterial" diet consisting of chicken fish ground meat cassards and vegetables.

dings, plum cake, toast, milk, fruit juices, finely milled cereals, macaroni, spaghetti and noodles. Pectin agar was given flavored and sweetened to suit the taste of the individual. It is best given with vanilla malted milk. Of the 24 patients 8, or 33% per cent, died in the hospital, 10, or 41.3 per cent, have apparently recovered from their intestinal disease, 2, or 8.3 per cent, are improving and still under treatment, and 4, or 16% per cent left the hospital before studies could be completed. The authors conclude that pectin agar is of decided value in controlling symptoms of intestinal tuberculosis.

Anticoagulant Therapy of Occlusion of Central Vein of Retina—Klien differentiates the following four types of occlusion of the central retinal vein 1 Occlusion by compression from without the vessel and secondary thrombus formation, as in some types of arteriosclerosis and phlebosclerosis or in tumor metastasis into the optic nerve In these conditions anticoagulant therapy is of little or no value, as thrombus formation is only the terminal event bringing about complete occlusion of an already narrow venous aperture 2 Occlusion by primary thrombus formation in blood dyscrasias, such as polycythemia and thrombocythemia Heparin or dicumarol therapy is of definite value The rapid action of these preparations may be prolonged and supported later, if necessary, by roentgen irradiation of the bone marrow 3 Occlusion by stagnation thrombosis following widespread arterial spasms To this type belongs venous occlusion caused by (a) early spastic hypertension, (b) a surgical procedure or cranial fracture and (c) congenital heart disease Anticoagulants, perhaps supported by vasodilators, should be of definite value in the treatment of this type 4 Occlusion by inflammatory disease of the venous wall and secondary thrombus formation The employment of anticoagulants is contraindicated Heparin and dicumarol are valuable additions to the therapeutic armamentarium for the care of eyes with venous occlusion whose vision otherwise might be lost, but the most accurate clinical classification of the type of occlusion should precede the employment of this therapy

Cortical Necrosis of Adrenal Glands Associated with Addison's Disease—Duffin states that Addison's disease is caused by a tuberculous destruction of the adrenal glands in the majority of cases There are, however, cases in which the process is not tuberculous They are referred to as cases of adrenal atrophy Relatively few such cases have been recorded in detail The author reports 8 cases and points out the remarkable similarity in their symptoms and course Six of the patients were women, the youngest was 20 and the oldest 44 at the time of death All presented a gradually developing and slowly progressing asthenia interspersed with attacks of prostration and vomiting All had some degree of hypotension and pigmentation All died in an Addisonian crisis but

two and four years after the onset of symptoms. The lesions observed in the adrenal glands presented the same striking similarity as did the clinical course. In 6 cases the lesion was one of cortical destruction with severe and widespread necrosis of the cortex in 4 and complete disappearance of cortical tissue in 2. In each case the adrenal medulla was comparatively well preserved but constantly showed lymphocytic infiltration. In 2 additional cases no adrenal parenchymal tissue remained, although the process was presumed to be of the same nature as that in the other 6. The thyroid was atrophic, fibrosed and infiltrated with lymphocytes. The pituitary gland in 3 of the 4 cases examined showed a diffuse increase in the connective tissue of the anterior lobe, a scarcity of basophils and a reduction in eosinophilic and chromophobe cells. A hitherto unrecorded pigmentation of fat tissue was noted. The process in the adrenal glands is not one of true atrophy but rather of a disappearance of tissue secondary to cortical necrosis. No clue as to the cause of the cortical necrosis was obtained. The incidence of this pathologic process in the present series of cases of Addison's disease was 41 per cent.

Post-Traumatic Dystrophy of Extremities—De Takats and Miller describe observations on the syndrome of Sudeck's atrophy. Many terms have been employed to characterize it such as traumatic angiospasm, chronic traumatic edema, acute atrophy of bone, post-traumatic osteoporosis, peripheral trophoneurosis and reflex nervous dystrophy. The authors studied and treated 33 cases in 12 plethysmographic studies the blood flow, vasomotor reactivity and calcium metabolism were investigated. They gained the impression that Sudeck's atrophy is the result of a chronic stimulation of somatic and possibly of efferent vasodilator fibers. Pain localized and spreading vasodilatation and osteoporosis characterize the fully developed syndrome but osteoporosis is a late manifestation. Reflex dystrophy is most amenable to treatment in the early stages; later it becomes more intractable and requires more radical interventions. The eliciting trauma is usually a blunt injury near a joint or a nerve trunk such as the interosseus, the saphenous or the posterior tibial nerve. The treatment must fit the duration and severity. It consists in repeated injections of procaine hydrochloride into the injured area, paravertebral sympathetic block, periaxillary sympathectomy and sympathetic ganglionectomy. Orthopedic correction may be needed in cases of advanced atrophy after the pain has subsided.

Refrigeration Prior to Amputation in Arteriosclerotic Gangrene—According to Halev, twenty amputations for arteriosclerotic gangrene have been performed in a six-month period at his hospital. Seven of these were performed under spinal anesthesia, 3 under intravenous pentothal sodium anes-

thesia and 10 with the employment of the ice-tourniquet anesthesia. The ice-tourniquet treatment has a place as a preoperative measure in the management of debilitated patients with gangrene. Operative or postoperative reactions following the use of this method are mild as compared with those following the use of spinal anesthesia. The need for preoperative and postoperative sedation is practically eliminated. The stump is apparently not harmed by the ice-tourniquet, and healing is satisfactory. The use of two tourniquets with amputation between them constitutes an improvement over the use of one tourniquet.

Alpha Hemolytic Streptococcus in Pneumonia—Thomas discusses 2 fatal cases of primary atypical bronchopneumonia. In 1 Streptococcus viridans was recovered from the sputum and from the blood stream during life. In the other the organism was recovered from the sputum during life and from the heart's blood and bronchial exudate at autopsy shortly after death. The presence of Streptococcus viridans in cases of influenzal pneumonia and primary atypical bronchopneumonia has been noted previously, but its importance has been discounted. The observations reported here suggest that this organism is capable of playing a pathogenic role as a secondary invader. In view of its well recognized pathogenic activity in the production of endocarditis, its presence in the bronchi in association with purulent inflammation may be of more significance than is at present recognized. Intense purulent broncholitides by causing obstruction of the air passages is an added factor in the symptomatology and outcome of atypical bronchopneumonia and Streptococcus viridans appears to be one of a variety of organisms which may produce this complication.

Coexistence of Pathogenic Fungi in Pulmonary Tuberculosis—Greer and Gemoets investigated the incidence of fungi in the oral sputum of 501 patients of the Houston Tuberculosis Hospital. Fungi were isolated from the oral sputum by direct smear and by culture on Sabouraud's dextrose medium in 11.75 (15 per cent) of 501 patients in 18 patients (6 per cent) and individually identical with the ones found in sputum were isolated by carefully controlled washing of the trachea. In the study of these 18 patients revealed that the fungi were

be found in the tracheal sputum of at least 4 per cent of tuberculous patients and that the finding of fungi in the oral sputum alone does not assure their presence also in the trachea and, therefore, by inference, in the bronchi and lungs. In 60 per cent of the patients who have fungi only in the oral sputum, the fungi are harmless saprophytic contaminants. Fungi obtained from the trachea and cultured on Sabouraud's dextrose medium will produce, when injected into the lungs of rabbits, localized and generalized pulmonary lesions from which the same fungi may be obtained. Pulmonary tuberculosis seems to have a more devastating course when it is associated with parasitic fungi. The coexistence of fungous and tuberculous infections should be more frequently considered in the diagnosis of chronic pulmonary diseases.

Methyl Testosterone for Simmonds' Disease—Werner and West point out that the loss of nitrogen after hypophysectomy in experimental animals is clinically reflected in Simmonds' disease, but, whereas in animals replacement therapy is readily accomplished with anterior hypophyseal substance, this is not always the case in Simmonds' disease. Administration of methyl testosterone in dwarfism results in nitrogen retention and creatinuria. The authors obtained striking subjective, objective and laboratory changes with methyl testosterone therapy in 4 patients with Simmonds' disease. The patients demonstrated renewed vigor, sense of strength and libido, and redeveloped secondary sex characteristics. Seborrhea failed to appear, suggesting that androgens act to produce seborrhea only after the skin has been prepared by some basic mechanism or mechanism in which are wanting following hypophyseal failure. In the absence of hypophyseal function, administration of methyl testosterone resulted in nitrogen retention associated with persistent weight gain. Definite creatinuria developed after a limited

period of several weeks and subsided in about the same length of time after discontinuance of treatment. The therapeutic value of methyl testosterone in Simmonds' disease or anterior pituitary insufficiency is suggested by these cases.

Absorption, Excretion and Distribution of Penicillin
—Rammelkamp and Keefer studied the absorption, excretion and distribution of penicillin when administered by various routes. The subjects included normal volunteers and ward patients. Penicillin in the form of the sodium salt was dissolved in either distilled water or 0.85 per cent sodium chloride solution and passed through a Sertz filter to effect sterilization. The final concentration of all solutions was 1000 Florey units per cubic centimeter except that administered subcutaneously which contained 200 Florey units per cubic centimeter of 0.85 per cent sodium chloride. The number of Florey units administered varied between 5000 and 40000. Intravenous injection of penicillin resulted in high initial concentration in the blood plasma followed by an abrupt fall. The sharp fall in the serum concentration was associated with increased excretion in the urine. Penicillin was rapidly absorbed when given intramuscularly and slowly absorbed after subcutaneous injections. Excretion in the urine was rapid following intramuscular injections and delayed after subcutaneous injections. Absorption from the body cavities was delayed and this was reflected in the slow excretion of penicillin by the kidneys. The total amount found in the urine was somewhat lower than that obtained after intravenous injection. Fluid aspirated from pleural and joint cavities twenty-two and thirteen hours after injection showed appreciable amounts of penicillin remaining. Absorption of penicillin from the duodenum was rapid, whereas oral and rectal doses were poorly absorbed. This may be explained by the inactivating effect on penicillin of the acid and of *Escherichia coli*. The average amount excreted in the urine after oral intraduodenal and rectal administration was extremely small. Penicillin was not excreted rapidly in renal failure and as a result high concentrations were maintained in the blood stream after intravenous injections. Penicillin failed to penetrate the red cells in significant amounts. The average concentration in erythrocytes was less than 10 per cent of the plasma concentration. No penicillin was found in the spinal fluid, saliva or tears of subjects receiving it intravenously.

Ascorbic Acid Content of Peaches—Schroder and others made a study of the ascorbic acid content of eight common varieties of peaches grown under comparable climatic and soil conditions in commercial orchards near Raleigh, N. C. The larger portion of the 156 peaches studied were obtained directly from orchards and were assayed within two days of their arrival. There was no correlation between the size of the peach and its ascorbic acid content. The average difference in ascorbic acid content of peaches within varieties was 4.29 mg. per hundred grams of fruit whereas the extreme difference between varieties was 902 mg. per hundred grams of fruit. The concentration of ascorbic acid in peaches was found to be highest in the skin, lower in the flesh directly under the skin and lowest in the flesh surrounding the pit. Hard, red, late

tained the minimum of ascorbic acid, and as the peaches ripened the amount increased to a maximum for the fully ripe edible peach. The average ascorbic acid content of ripe peaches varied from 384 mg. per hundred grams for the Augbert to 1286 mg. per hundred grams for the Hiley Belle variety. The ascorbic acid content of peaches is not as high as that of lemons, oranges or tomatoes, but fully ripe peaches contain sufficient ascorbic acid to contribute materially to the human requirements for this vitamin.

Repeated Administration of Sulfonamides in Children—Link and Wilson investigated the incidence of acquired sensitivity to sulfadiazine and sulfathiazole in 177 children who were given a sulfonamide drug in two or more courses and had no reaction during the first course. Of the 86 who were given sulfathiazole 3 developed febrile reactions, and of the 91 who were given sulfadiazine 4 developed febrile reactions. It is suggested that these febrile responses were toxic reactions to the drug that might have occurred at any time and had no clear relation to previous drug therapy. Two of the 7 children with initial reactions were given a second and a third course of the drug without reaction. An "immediate" type of febrile reaction occurred during a second course of sulfonamide in 3 of 5 children who had had reactions during a first course. These studies showed that "sensitization" to sulfathiazole or sulfadiazine is not common or frequent in children but that the occurrence of one reaction greatly increases the probability of future reactions. The authors suggest that children who develop toxic symptoms during the first administration of the drug should be given the drug only with caution and under close observation.

Congenital Goiter in Infant with Recovery Following Operation—Davies presents the history of a woman who gave birth to 7 children, 5 of whom are alive. The first three were normal full term males and are now 11, 10 and 7 years of age respectively. The mother has had severe attacks of asthma since 1934. She administers to herself injections of epinephrine during these attacks. She has a centrally placed thyroid swelling of small to medium size which appears to be adenomatous in character. At the birth of the fourth child the mother was acutely distressed with an attack of asthma, and epinephrine had to be given. The infant was dyspneic and cyanotic. A large bilateral mass connected by a smaller central mass occupied the greater part of the anterior neck. This child died on the thirteenth day. The postmortem diagnosis was congenital hyperplasia and hypertrophy of the thyroid. The fifth child died when 27 days old. The case of this child resembled that of the preceding one, although the swelling in the neck was unilateral. The sixth child, a girl, presented no enlargement in the neck at birth and is normal at the age of 2. The seventh child, a boy, was born on Nov. 22, 1941 with a large bilateral mass in the neck. One-third grain (0.02 Gm.) of sodium iodide in aqueous solution was given by mouth once a day, beginning on the third day of life. Four days later the swelling in the neck appeared to be enlarging. On December 4 thyroidectomy was performed because of cyanosis and stridor. Two minims (0.12 cc.) of strong solution of iodine was given daily for the next twelve days. There is no evidence of thyroid disturbance several months after the operation.

Primary Atypical Pneumonia—Thompson's report deals with 250 cases of a syndrome which has been variously termed "acute diffuse bronchitis," "acute interstitial pneumonitis," "acute pneumonitis," "virus pneumonia," "primary atypical pneumonia" and the like. The pneumonitis is mainly interstitial. The criteria for diagnosis are a history of "grippy" sensations, minimal physical signs, x-ray findings, normal or leukopenic white blood cell response, irregular fever resolving by lysis, relative bradycardia, sputum negative for pneumococci and no response to sulfonamide therapy. The etiologic agent may be one of several viruses, and the clinical signs and symptoms form a bizarre pattern. A definite diagnosis can be made through totaling several factors and not by a single observation or procedure. Exclusion of closely simulated diseases, particularly of pneumococcal pneumonia, is paramount. There is no alternative but to give a sulfonamide routinely until a definite diagnosis of primary atypical pneumonia can be made. This routine therapy at the onset of the disease might have some beneficial effect on possible secondary bacterial invasion. Symptomatic treatment is all that can be offered in primary atypical pneumonia. The symptoms that demand greatest attention are the headache and the dry, hacking cough. These are alleviated by codeine and by steam inhalations. Oxygen therapy is rarely necessary. The author kept each patient at bed rest until there had been six days of normal temperature or until the x-ray film showed clearing. Seven to fourteen days of fever, six days of normal temperature, seven days sitting up and seven days of moderate activity resulted in an average hospitalization of between twenty-seven and thirty-four days. This lengthy convalescence is believed to be a major factor in the lack of serious complications in this series.

Allantoin-Sulfanilamide-Lactose Ointment in Infections of Cervix, Vagina and Vulva—The ointment used by Parks contains 2 per cent allantoin, 15 per cent sulfanilamide and 5 per cent lactose in a special greaseless base buffered to a pH of 4.5 with lactic acid. A total of 68 patients have been treated with this preparation. Surface infections of the cervix, vagina and vulva, with the exception of vulvo vaginal mycoses, respond to local applications of the ointment. Its expression through a tube into the vaginal vault is a quicker

Antral Mucosa in Surgical Treatment of Duodenal Ulcer—Allen states that approximately 80 per cent of the patients coming to the Massachusetts General Hospital with duodenal ulcer are satisfactorily treated by conservative measures. Surgical ulcers, except acute perforation must be treated radically. Conservative operations give a high incidence of poor results and should be abandoned. Complete elimination of the antral mucosal cells is necessary for the highest degree of success. This can be accomplished by the resection of the distal half to two thirds of the stomach. When technical difficulties make this unsafe, the antral mucosa should be removed in any segment left for adequate closure. It is by these methods that the most serious complications of inadequate operation, namely anastomotic or jejunal ulcer, may be prevented.

Chemotherapy in Penetrating Abdominal Gunshot Wounds—Loria reports a group of 100 cases of penetrating gunshot wounds of the abdomen admitted to the New Orleans Charity Hospital. Forty-nine received some form of chemotherapy, while 51 did not. In the chemotherapeutically treated group the mortality was 18.4 per cent. In the group not so treated the mortality was 50.9 per cent. In a group of 11 patients in whom intraperitoneal implantation of sulfathiazole

was practiced there were no fatalities. Sulfathiazole was the drug used. None of the patients so treated showed any evidence of toxicity attributable to these drugs. Peritoneal fluid concentrations were not determined, since none of the patients were drained. A small number of blood level determinations of the drug failed to show high figures, although large doses were implanted intraperitoneally. The sulfonamides are especially helpful to patients showing "massive" hemorrhage. Such patients showed a 91.6 per cent mortality in the group receiving no chemotherapy, as compared with 40 per cent fatality in the group receiving sulfonamide treatment.

Postoperative Radiotherapy of Carcinoma of Breast—McWhirter states that when surgery is the only method of treatment available survival for five years probably does not occur in more than 1 in 5 of all cases of cancer of the breast. The three year symptom free rate is a reliable guide to the five year survival rate. A total of 1879 cases has been analyzed. In the operable group (stages 1, 2 and 3) effective postoperative radiotherapy by destroying cells left behind in the treatable area results in much higher three year symptom free rates in all three stages. Postoperative radiotherapy is still effective when the disease has spread to the axillary glands but is of no value so far as survival rate is concerned if the disease has spread to distant sites. Simple mastectomy combined with postoperative radiotherapy as a method of improving results and as a means of diminishing disability is on trial. Survival to five years in the advanced (stage 4) group is so low as to be accidental irrespective of the method of treatment. The delay which occurs between the time the patient first notices something wrong and treatment is on an average nine months. Treatment before the stage of clinical certainty is reached is strongly advocated if further progress is to be made. At the early highly curable stage a clinical differential diagnosis should not be attempted. Excision and microscopic examination is the only reliable means of diagnosis. If medical delay is eliminated the cure of at least 1 out of every 2 or all cases of cancer of the breast is easily possible with methods of treatment at present available.

Emergency Medical Service R J Blackham—p 199

Acute Syndrome Following Sulfanilamide—Murley describes a case in which an acute fulminating hemolytic syndrome developed following the administration of 12 Gm of sulfanilamide to an Indian sepoy with multiple venereal sores. Fat necrosis of the liver and acute necrotizing nephrosis accompanied the hemolytic syndrome. The much dreaded agranulocytosis is a complication or prolonged or injudicious dosage in

the great majority of cases. Agranulocytosis is a late complication of chemotherapy and is rarely seen when the drug is carefully used. Acute hemolytic anemia, however, is an early complication which is unrelated to incautious use of the drug and may occur in the hands of the most careful clinician. The importance of exercising adequate caution in chemotherapy is stressed.

Penicillin and Propanidine in Burns—Clark and his associates point out that the predominant part played by the hemolytic streptococcus and the staphylococcus in interfering with the repair of burns makes it desirable to perfect means for preventing and controlling infection by these organisms. Sulfanilamide is not quite the ideal agent for this purpose. The authors applied penicillin in the form of a cream to 54 burns and scalds in various stages of healing. In 41 of the wounds (76 per cent) the streptococci disappeared within five days and did not reappear. In 7 the strains which promptly disappeared were insensitive to the sulfonamides. There were no cases in which penicillin appeared to have no effect. Staphylococci also disappeared quickly from many of the wounds. Healing was rapid and no toxic effects were observed. Propanidine was applied in the form of a cream (0.1 per cent) to 34 similar burns. Hemolytic streptococci disappeared within five days from 21 of the wounds (62 per cent). They persisted in 8 cases during treatment with propanidine. Of these 3 lost their streptococci promptly when they were later treated with penicillin. Healing was not quite so rapid as with penicillin. No toxic effects were observed. Coliform bacilli *Proteus vulgaris* and *Pseudomonas pyocyanea* when present in the wounds were apparently not affected by either agent.

Treatment and Prevention of Thrombosis—Lehmann of Gothenburg, Sweden gave dicumarol the anticoagulant first obtained from spoiled sweet clover hay by mouth to 100 persons with established venous thrombosis in the lower limb and 32 with thrombophlebitis. In thrombosis the mean recovery time was reduced to from one to three weeks, a third or what it was before anticoagulants were used and in thrombophlebitis to six and one half days. The anticoagulant was also given prophylactically to 170 patients after various gynecologic operations during 1942. Only 1 case of venous thrombosis and 1 mild case of embolism were seen and there were no deaths from these causes. In 1941 there had been 9 cases of thrombosis and 5 of embolism with 3 deaths in a comparable series. In about 1 case in 10 hemorrhage occurred as a complication but in only 1 in 100 was it at all profuse and in these it was readily controlled with vitamin K and blood transfusions.

 Electroencephalography in Man M. Monnier—p 1253

Parodontitis in Early Diagnosis of Diabetes—Grott surveyed 350 patients with diabetes for the presence of parodontitis. Particular attention was paid to looseness of teeth and to the length of time these symptoms existed before the discovery of the diabetes. It was found that 148 of the patients had loose teeth, 34 others had symptoms of parodontitis without looseness of teeth. Of a total of 350 patients, 182 (52 per cent) had had changes in the parodontium before diabetes was recognized. In 80 of the 148 patients the symptoms of parodontitis antedated the discovery of diabetes by from one to five years and in 68 by five years. These figures indicate that symptoms of parodontitis can be of value in the early diagnosis of diabetes. If no sugar is detected in the urine in the presence of a parodontitis a tolerance test should be made and the blood sugar curve investigated.

Coronary Sclerosis in Young Persons—Walthard reviews the causation of coronary sclerosis, he studied 18 cases. Two cases of endocarditis lenta are intentionally included in order to demonstrate the insignificance of a mycotic inflammatory process for the genesis of coronary sclerosis. The remaining 16 are typical cases of coronary sclerosis in persons between the ages of 20 and 40. Postmortem examinations were negative as to the existence of a focal inflammation. The structure of the intimal plaques in the endocarditis lenta cases with the mycotic infectious foci was the same as in other cases of arteriosclerosis. It was not possible to establish a relation of focal inflammation to the development of a narrowing coronary sclerosis, an inflammatory sclerosis. The concept arteritis stenosa coronariae should be rejected. The process in question is not a primary inflammation in the form of an infection but rather a reparative secondary inflammation in the course of a progressive coronary sclerosis that leads to contraction of the artery.

- Chorea in Children A. M. Abril—p 69
 *Cruveilhier-Baumgarten Syndrome (Jaundice Due to Sclerotic Hepatitis) in Infant Case A. Castellanos—p 86

Cruveilhier-Baumgarten Syndrome—According to Castellanos, congenital jaundice due to sclerotic hepatitis (the so-called Cruveilhier-Baumgarten syndrome) is extremely rare in infants. The main symptoms are portal hypertension with consequent enlargement of the superficial veins of the portal system, hepatomegaly, splenomegaly, functional liver insufficiency and jaundice. The abdomen is balloon-like, the umbilicus is herniated, the face is puffy, the epicranial and cervical veins are enlarged and the fingers are clubbed. The physical and mental development of the patient is delayed. The diagnosis is confirmed by a puncture biopsy of the liver. The liver presents adult connective tissue and local sclerosis. The therapy consists of antisyphilitic drugs, regardless of whether the serologic tests of the infant or of the parents are negative. The case reported by the author in an infant of 22 months is the third on record in world literature. The patient was improved by antisyphilitic therapy.

- Encephalitis After Vaccination D. Fleury Silveira—p 167
 *Auricular Herpes Zoster Cases L. de Assis and P. da Cunha Cintra—p 179

Auricular Herpes Zoster—Localization of the virus of herpes zoster in the geniculate ganglion is rare. It produces the so-called Ramsay-Hunt syndrome, which manifests itself by facial paralysis and cutaneous vesicles or pustules along the external auditory canal and the pinna. The neurologic symptoms may appear either early or late in the course of the disease, or during regression of the cutaneous and mucosal lesions. The pure form of the disease is benign. The symptoms slowly regress and disappear completely in from two to four months. The therapy consists in intense administration of vitamin B. Faradization is applied to the muscles two or three weeks after the appearance of paralysis. The appearance of muscular contractions in the course of the electrical therapy calls for discontinuation of faradization. Salicylates and strychnine by mouth or injection are helpful. Sulfamidamide is useless and dangerous because of its toxic effect on the peripheral nerves. Two cases are reported.

 Use of Preserved Complement in Serodiagnosis H. Gross and G. Henning—p 136

Bacterial Growth and Its Prevention in Preserved Blood—Reissmann detected bacterial contamination in preserved blood which showed no hemolysis and in which the Duran-Jorda test had failed. The fact that the transfusion of preserved blood caused chills and rise in temperature in a larger percentage of cases than transfusion of fresh blood induced him to make a bacteriologic test of every unit of preserved blood. The tests revealed that about 6 per cent of the units of preserved blood were contaminated, chiefly with staphylococci. This high percentage and a severe reaction in 1 patient who was given a transfusion of preserved blood which was found to contain colon bacilli induced a search for a disinfecting substance. Tests were made with several sulfonamide preparations, with propyl-hydroxybenzoate and related substances and with acridine dyes, such as rivanol and acriflavine hydrochloride. Rivanol gave the best results. When 2 mg of rivanol was added to 100 cc of blood, the majority of contaminating bacteria were either killed or inhibited and no harmful effect was exerted on the blood. Preserved blood which contained this addition was well tolerated and its effect did not differ from other preserved blood. The author's studies were made in the course of the preparation of 4,000 specimens of preserved blood.

Serologic Behavior of Keratitis Parenchymatosa—Schmidt's observations on 34 cases of parenchymatous or interstitial keratitis did not corroborate the widely held opinion that the strongly positive serologic reactions are about equally frequent in keratitis patients of all age groups and that they show the same refractoriness to specific treatment in adults as in children. He found that intensely positive reactions are most frequent in patients between 10 and 15 years of age. The frequency of the intense reactions decreases with age. Only about half of the patients in whom interstitial keratitis develops after the twenty-fifth year show strongly positive serologic reactions. The prospects of conversion of the positive serologic reactions into negative by the antisyphilitic treatment are much better in patients over 20 than in children. One series of antisyphilitic treatments failed to produce negativity in all or 4 children less than 10 years old and in 19 of 20 children between 10 and 20, but in only 6 of 10 patients in the third and fourth decades of life.

Book Notices

Compendium of Aviation Medicine By Siegfried Ruff and Hubertus Struhschold [English translation] With introduction by Surgeon General Prof. Dr. Erich Hippke Chief of the Medical Staff of the German Air Corps. Reproduced under a license granted by the Alien Property Custodian 1942. Paper. Pp. 130 with 103 illustrations. Washington D. C. National Research Council 1942.

This book was offered in 1939 as a practical textbook for aviators, medical students and physicians concerned with medical problems in aviation. The authors point out that German aviation medicine has not been content with practical research alone but has also boldly attacked the scientific fundamentals of the problem. Their object has been not to prepare an exhaustive source book for specialists but rather to present to the medical profession at large a body of information concerning the results of these investigations and to make accessible a cross section of the status of contemporary medical aviation. Both authors are particularly well qualified for this task having made important contributions to research in several aspects of aviation medicine. In spite of its modest aspirations, this book constitutes a significant contribution to the subject. Although three years old and despite the welter of open and confidential literature which has since become available this work is of special value in the English language because of the early and extensive preoccupation of the Germans with aviation medicine.

The present translation has been reproduced under a license granted by the alien property custodian. The translator has prepared the text in an attractive and readable style and has at the same time faithfully preserved the sense and form of the original. The illustrations and text have been adequately prepared by the National Research Council within the limits of the planograph technique.

Dr. Erich Hippke, Chef des Sanitätswesens der deutschen Luftfahrt, who has written the preface, refers to the book as comprehensive. However there are notable omissions. Specifically the reader finds no discussion of vision, hearing, alimentary or renal function or the endocrine glands in relation to aviation. Nor are bacteriology and immunology in aviation, decompression sickness (bends), pathology of aviation selection testing and sanitary aviation included. In view of current interest the absence of consideration of the bends is especially surprising but possibly significant.

Chapter I reviews the historical background of aviation medicine. The treatment is sketchy, surprisingly so considering the rich historical bibliographic material available to the authors in Schmidt's *Bibliographie der Luftfahrtmedizin*. Chapter II contains a well written discussion of the effects of altitude on the body. There is an excellent section on the physics and chemistry of the atmosphere. Research methods and terminology in aviation medicine are briefly reviewed. Then follow sections on the blood, respiration, the circulation and the central nervous system. The effects of altitude on consciousness and reflex behavior are touched on. Altitude tolerance is treated in some detail. Physical, biologic, dietetic and pharmacologic factors in determining the body's resistance to flight conditions are discussed. The chapter closes with a consideration of acclimatization and the possible biologic effects of cosmic rays. Chapter III is a review of the effects of linear, radial and angular acceleration on the organism. Problems raised include the effects of opening the parachute, launching the plane from the catapult, directional changes in the plane and rotation in the centrifuge. In chapter IV is given a very incomplete account of sensory physiology in flight. Chapter V contains an analysis of the causes of flying accidents and in chapter VI, under the title of comparative physiology of flight, the wing structure and action of birds are described. The physiologic adaptations of the lower animals to high altitudes—of considerable intrinsic interest as well as practical importance in sanitary aviation—are not discussed.

Throughout the text the effects of flight on the body are considered in the light of normal physiologic mechanisms and wherever necessary the reader is given lucid explanations of physical and mathematical principles involved. The lack of an index is to be deplored.

Sevilles The Art of Compounding By Justin L. Powers, Ph.D. Chairman of the Committee on National Formulary and George E. Crossen, Ph.D. Dean and Professor of Pharmacy, Drake University, Des Moines. Seventh edition. Fabrikoid. Price \$4.75. Pp. 457 with 57 illustrations. Philadelphia: Blakiston Company 1943.

This edition presents an improved and modernized textbook for students in dispensing pharmacy. The authors have adjusted the length and content of many of the chapters to conform with changing methods and improved practices. The sequence has been somewhat revised to provide a more logical and desirable order for the presentation of the material. The first chapter deals with the origin and structure of the written prescription and describes its reception, checking, compounding, labeling, pricing and filing by the pharmacist. The second chapter discusses nomenclature, vocabulary and Latin terms and their abbreviations. The consideration of incompatibilities has been expanded into three chapters and the material has been rearranged. Improved arrangement is especially evident in the chapter on chemical incompatibilities in which the cations are grouped according to their positions in the periodic table so that the student can use his knowledge of chemistry to better advantage. The consideration of incompatibilities has been moved forward. From the standpoint of usefulness this change in order is a very desirable one. While it may tend temporarily to cloud the student's perspective or prescription dispensing, it should result in a clearer understanding of the material covered in succeeding chapters. Chapters 6 to 9 deal with various solutions. The material on isotonic solution especially is presented in a clear and understandable manner. A general discussion of hydrogen ion concentration and its application to the preparation of buffered solutions is included. However the application of buffering to specific groups of solutions would have been valuable to the student. For instance medical schools teach that collyriums should be buffered but pharmacy students and pharmacists would have difficulty in preparing buffered collyriums from the information in the text. Succeeding chapters cover the various types of pharmaceutical preparations and prescriptions. The chapter on pills is probably too lengthy for present needs of pharmacy and medicine. Emulsions are discussed comprehensively but the reader has difficulty in finding the meaning of an o/w or w/o emulsion without searching for the scattered threads of the explanation through a number of paragraphs. Chapters on vitamins and biologic products are brief but adequate. Chapter 23 on sterilization is very complete but the sterilization of certain sulfonamides for intraperitoneal and external use as bacteriostatics is not mentioned. With the added material the change in chapter sequence and improved style this edition should be of greater usefulness than the sixth to students in pharmacy and to practicing pharmacists.

Synopsis of Traumatic Injuries of the Face and Jaws By Douglas B. Parker, M.D., D.D.S., Associate Professor, Department of Oral Surgery, School of Dental and Oral Surgery, Columbia University, New York. Fabrikoid. Price \$4.50. Pp. 334 with 229 illustrations. St. Louis: C. V. Mosby Company 1942.

The presentation of this book achieves the author's desire to provide a concise well illustrated manual for the medical and dental professions on the subject of face and jaw injuries of traumatic origin. The author states that it was not his intention to produce a textbook on oral surgery or plastic surgery but rather in a synopsis form to present the treatment of maxillofacial cases from first aid at the scene of injury to the more definitive treatment at a more permanent base.

Physicians and dentists join their efforts in the treatment of maxillofacial cases. This cooperation and team work can be expected to assume an important role in this war and the years to follow. A number of special courses of instruction in maxillofacial surgery have been given in the military service, civilian institutions and organizations. The attendance at these courses clearly indicates the earnest desire of surgeons and oral surgeons to improve themselves professionally and to obtain a more adequate training in basic and emergency surgical procedures.

Adequate first aid and early treatment of face and jaw casualties is encouraged as a means of effecting their return to duty as soon as possible. Inadequate or delayed treatment may contribute to prolonged hospitalization and unusually difficult

Queries and Minor Notes

THE ANSWERS HEREF PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TYPHOID VACCINATION AND TUBERCULOSIS

To the Editor—Is typhoid vaccine contraindicated in clinically active tuberculosis? Is it contraindicated in arrested tuberculosis?

J. D. Riley, M.D., State Sanatorium, Ark

ANSWER—Any insult to the constitution of a patient suffering from active tuberculosis without a compensatory beneficial effect will be detrimental. As typhoid vaccination sometimes produces severe reactions and as beneficial effect on tuberculosis has never been claimed, it follows that it will probably result in injury which may lead to serious results. Although Baldwin and L'Esperance failed to show any particular damage in guinea pig experiments following typhoid vaccination, Clovis and Mills reported the production of acute pleurisy resulting from its use in tuberculous patients. There is every reason to believe also that it will produce irritation and exudation elsewhere in the body of tuberculous patients. In a report by Hektoen and Irons, who canvassed 267 American specialists in tuberculosis, there were over 3 to 1 who claimed unfavorable over favorable results on the use of different "vaccines" (not counting products of the tubercle bacillus) in tuberculous patients. Although the vaccines were intended for the "secondary infections" and were not "typhoid," the principles are similar if not identical. Of the favorable claims made to these authors only vague "good results" were reported, while from those reporting unfavorable results five deaths were directly attributable to "mixed stock vaccines."

For quiescent, latent-active or "arrested" tuberculosis it would seem that the same general rules should apply. There is a period of years when the bacilli are being encapsulated, when a sudden exudative reaction may cause a softening and exacerbation of the lesion.

In the population there is a large number of infected people who are either drifting toward disease or toward recovery when a rupture of an encapsulated tuberculous node or tubercle into the tissues or into one of the canals may lead to active and even fatal disease. There are many "accidents and shocks of life" which have been found to precipitate disease in such patients, not the least of which is typhoid vaccination. In the writer's experience activity has been precipitated in two definite instances by typhoid vaccination. Hench also reports a few random cases of exacerbation of tuberculosis following typhoid vaccination.

It seems prudent, therefore, to refrain from vaccination against typhoid in all cases of active tuberculosis and in all latent-active cases (such as those the Army and Navy reject for tuberculosis) except where the danger of typhoid itself greatly outweighs the probability of active tuberculosis. An example of the latter condition is afforded by invaded countries or bombed cities where enteric diseases may be rampant.

FLUORIDES AND DENTAL CARIES

To the Editor—What type of fluorine and what dose is necessary to use as a preventive of tooth decay? Lieutenant Colonel, M. C., A. U. S.

ANSWER—There is a large amount of epidemiologic evidence suggesting that an optimal intake of fluoride tends to inhibit the intensity of dental caries attack. In this country differences in dental caries prevalence rates have been found associated with differences in the fluoride concentration of several municipal water supplies studied. In what particular form the fluorine is present naturally in these waters has not been satisfactorily demonstrated but experimentally several of the salts of fluorine (sodium fluoride, calcium fluoride and others) have been shown definitely to inhibit induced caries in rat molars.

The specific dosage most useful in inhibiting dental caries attack in man has not been definitely determined. A paper by F. J. McClure, recently accepted for publication by the *American Journal of Diseases of Children*, entitled "Fluoride Ingestion and Dental Caries—Quantitative Relations Based on Food and Water Requirements of Children 1 to 12 Years Old," may answer theoretically some of the questions raised in connection with the problem of dosage or fluoride intake.

On the basis of epidemiologic studies made in eight suburban Chicago communities (*Pub. Health Rep.* 56: 761 [April 11] 1941) it would seem that the most desirable fluoride concentration in a domestic water from the standpoint of dental health, is one containing about one part per million of fluoride (F). It is of course, likely that in some regions of the United States, for instance the Southwest, where climatologic conditions such as high mean annual temperature, humidity and wind velocity may introduce factors conducive to a higher water consumption and consequently higher fluoride intake, low dental caries prevalence rates may be found associated with the continued use of domestic waters well below one part per million. A specific answer to possible climatologic influences, however, must await the results of a number of detailed epidemiologic studies in different parts of the country in cities having the requisites for quantitative evaluation. The probable influence of this variable, therefore, must be kept in mind, a relatively precise estimation of its influence must await the results of further study.

The control of dental caries attack through the medium of internally administered fluoride has not as yet been subjected to a controlled test. No information, therefore, is available with regard to whether fluoride administered in this manner will or will not reduce the incidence of dental caries.

MANUFACTURE INVOLVING FORMALDEHYDE COMPOUND

To the Editor—A local manufacturer of wallboard is contemplating the manufacture of a new product which involves the application of a formula consisting of urea, formaldehyde and ethylene glycol. This formula will be painted on the rough board and then subjected to heat in a closed oven and later to certain presses. The question arises as to the danger to employees from inhalation of fumes from this mixture and the possible danger to residents surrounding the factory from the escape of fumes into the atmosphere from the oven. I have no literature available locally on which to base an opinion as to the harmful effects which might result from the inhalation or contact with these fumes. Can you give me any information available on this subject and, if they are harmful, any suggestion as to means of protecting the workmen handling this mixture and also the escaping fumes from the factory?

Archie Orenstein, M.D., Hilo, Hawaii

ANSWER—This query lacks some items of information necessary for a satisfactory answer. It is not clear that the urea-formaldehyde combination represents one of the well known urea-formaldehyde condensation resins or instead a loose mixture along with ethylene glycol, which possibly are chemically combined in the product itself as a result of heat and pressure. Further, the extent of operation is not clear, which fact is important to the scale of community atmospheric pollution. In any event the formaldehyde is the item for chief practical consideration. There is every reason to believe that enough formaldehyde may be present to constitute objectionable or damaging work conditions within the factory unless the operations mentioned are carried out mechanically in enclosed systems, which is highly desirable. The threshold of beginning injury from formaldehyde is about 10 parts of the gas per million of air. Above that level, and more particularly above the level of 20 parts per million, respiratory irritation may be expected, which in severe form is characterized by bronchitis and at times respiratory tract abscesses. Skin contact with almost any material containing formaldehyde may lead to dermatitis. The situation will be less troublesome if in fact a preformed urea-formaldehyde synthetic resin is employed. No casual protection such as that from respirators would be sufficient in case considerable volumes of formaldehyde gas are present. Full consideration should be extended to the merits of well ventilated automatic operations. Apart from the fabrication of the products, some possibility exists that sawdust from later shaping of the wallboard may lead to skin irritation.

As to the community situation, some benefit may arise from the passing of the entrained gases through a water screen or sprinkler system, since some of the gases evolved are readily dissolved in water and may be discharged into waste system. Assuming the provision of fairly high stacks, the dilution of the formaldehyde would be so great as to eliminate community hazard, but odors probably would arise. Formaldehyde odors are disturbing to most persons. A somewhat analogous situation exists in connection with the fabrication of bakelite products, bakelite being a phenol-formaldehyde resin. While no real damage is done, disturbing odors are sometimes encountered for several blocks down wind. Both in the factory and in the

general atmosphere it will be necessary to maintain conditions as to formaldehyde below the 10 parts per million level. Measurement procedures may be found in an article by Barnes and Speicher in the *Journal of Industrial Hygiene and Toxicology* 24:10 (Jan) 1942

EFFECT OF ESTROGEN ADMINISTRATION IN EARLY PREGNANCY

To the Editor—A white woman aged 30 was brought to me by police eighteen hours after having been raped. She expected to menstruate in fifteen days. The legal questions and the question of prevention of disease are not difficult to handle but the question of the prevention of pregnancy entirely apart from the moral aspect has confused me and led to violent disagreement among my friends. I was advised to give large doses of estrogenic substance 50,000 units in oil daily for the three days prior to her expected period and on the day of the expected period to give quinine and cod liver oil. As menstruation may be due to withdrawal of estrogen it can be argued that this is not logical. I have decided partly on moral grounds to do nothing but wait and see nevertheless the paucity of information on this question irritates me. Textbooks and the literature seem to avoid the point deliberately. What can be expected if large doses of estrogen are given to a nonpregnant woman immediately prior to her expected menses? If they are given to a pregnant woman prior to the date on which should she not be pregnant she would have menstruated? If they are given to a woman during the early months of pregnancy? I should also like to know in the consideration of similar situations how the possibility or probability of pregnancy can be estimated.

M.D. Maryland

ANSWER—Large doses of estrogenic substance given to a nonpregnant woman immediately prior to her expected menses will usually have no effect on the ensuing period, since once the menstrual cycle is in full swing the rhythm is hard to upset. On the other hand when large doses of estrogenic preparations are administered in the first half of the cycle and continued throughout the next menses are often delayed. Thus Zondek (*THE JOURNAL* May 11, 1940, p 1850) has been able to postpone menstruation from seven to seventy days in this way the dose necessary for bringing about such an effect is at least 70,000 international units. This inhibition of menstruation it is believed results from the fact that the estrogen blocks the gonadotropic action of the anterior pituitary, whereby the development of the corpus luteum and production of progesterone are prevented. Consequently the uterine mucosa cannot develop and progestational transformation does not occur.

Whether the administration of estrogens to a pregnant woman between the time of conception and her first missed period would prevent implantation by disrupting the preparation of progestational endometrium (as described in the query) is not known. When given in pregnancy after the first missed period even large doses of estrogen are completely ineffectual in interrupting pregnancy.

Since rape occurred in this case about the time at which ovulation would normally have taken place that is fifteen days before the next menstruation the probability of pregnancy is good. The moral issues concerned in a problem of this kind depend so much on the circumstances of the individual case that generalizations are impossible.

UVULECTOMY

To the Editor—Is the operation of routine uvulectomy with tonsillectomy and adenoidectomy considered good practice? Is it an accepted procedure? Would it be free from a malpractice suit? Would the anesthetist giving the anesthetic be involved in such a suit? The uvulas being removed are perfectly normal.

M.D. Washington D.C.

ANSWER—The operation of routine uvulectomy (staphylectomy) with tonsillectomy and adenoidectomy is not considered good practice. It is not an accepted procedure. Abstracts of a number of court cases have been published in *THE JOURNAL* in which physicians have been sued for malpractice based on the removal of the uvula or a part of it during tonsillectomies.

Schmid & Stone 194 W 917 abstracted in *THE JOURNAL* March 15 1934 page 915

Goran & McCord 11 P (2d) 141 abstracted in *THE JOURNAL* Jan 14 1933 page 140

Shuffield & Taylor 83 S W (2d) 955 abstracted in *THE JOURNAL* Jan 4 1936 page 72

Thomas & Burgess 79 P (2d) 136 abstracted in *THE JOURNAL* April 1 1939 page 1291

The foregoing cases are evidence of the possibility that suit may be instituted against a physician who removes the uvula during a tonsillectomy without the knowledge and consent of the patient. An anesthetist normally is not legally responsible for the dereliction of the operating physician. Where a uvula is so large as to give symptoms of pharyngeal discomfort, cause cough or otherwise irritate the larynx and pharynx or interfere mechanically with the functions of breathing, swallowing and

nutrition, the exact condition of the uvula should be positively determined. Inflammatory, specific, neoplastic, indurative, infiltrative and degenerative states of the uvula must be proved so that the physician in attendance and in charge of the patient will be able to discuss the condition with the patient's parents or with the patient himself, if he is an adult past his majority, and to state specifically just what he proposes to do to the uvula during the operation. There are certain instances when a partial uvulectomy is warranted but the consensus of rhinolaryngologic opinion throughout the world is to leave a normal uvula alone. This brings up another point that happens every now and again in practice. A portion of a normal uvula may be inadvertently mipped during the time the tonsils are removed and not infrequently the entire uvula has been snared off. The latter surgery is unfortunate and should be considered an accident and though no deleterious effects have been particularly noted it is a practice to be studiously avoided. If during the course of a tonsillectomy a portion or an entire uvula has been severed inadvertently, the parents or guardian should be told about it and a complete explanation given. Uvulectomy has been performed inadvertently by skillful laryngologists as the result of dense adhesions that may have not been completely divided or dissected. The normal uvula should be left alone; the abnormal uvula should be treated according to indications.

SCRUB DERMATITIS—POSSIBLE SENSITIVITY TO FORMALDEHYDE AND RUBBER

To the Editor—I have been suffering from a so-called scrub dermatitis since 1935. Clinically I am sensitive to formaldehyde although patch tests are inconclusive. In 1935 I spent many days in the cystoscopic room wearing gowns sterilized in formaldehyde vapor cabinets. The gowns fitted snugly about my wrists under rubber gloves. The onset of the dermatitis was about my wrists but later extended to the backs of the hands and forearms. After the acute episode of three or four months the dermatitis took a mild and intermittent course but during the past year it has been present almost continuously. I found crude tar effective at first but later it became irritating. It responds most favorably to x-rays. Elimination of the common foods known to be allergenic has not been helpful. The past several years I have used nothing but Duke's basic soap for scrubbing which has been of some value and recently I have been using sulfonated oil to replace all soap without real benefit. I have not eliminated formaldehyde and still use a formaldehyde vapor sterilizing cabinet for cystoscopic instruments. In the past month or two I have developed a contact dermatitis over the right eye where the bakelite ocular of the cystoscope rests during cystoscopic procedures. Instruments are always washed with sterile water after being removed from the formaldehyde cabinet. Recently I have tried neutralization by immersing the instruments in a diluted hypochlorite (1/2 per cent Dakin's) solution before putting them through the sterile water bath.

I wish to continue vapor sterilization of cystoscopic instruments if at all possible because of the convenience of this method. Is there any other antiseptic vapor which could replace formaldehyde? If not is there any better way to detoxify the formaldehyde? Does the bakelite ocular of the cystoscope absorb the formaldehyde vapor and if so would a metal ocular solve this particular problem? If it becomes necessary to eliminate the formaldehyde cabinet and go to liquid sterilization what solution would give adequate sterilization yet be the least irritating to the skin? I understand that Bard-Parker's solution contains formaldehyde. Assuming that scrubbing and soap play a part do you have any suggestions in this respect? What part might rubber gloves play and if important how could the gloves be treated to remove the irritant properties? Would attention to vitamins or diet be of any value? What sequels might be anticipated in continuing x-ray therapy which is now effective?

M.D. Nebraska

ANSWER—Formaldehyde is not only a primary skin irritant but is one of the most powerful sensitizers and many physicians as well as laboratory technicians are highly sensitive to it.

No cold vapor other than formaldehyde is used to disinfect instruments.

Formaldehyde can be oxidized with an oxidizing agent like hydrogen peroxide, sodium perborate or potassium permanganate in solution.

Bakelite is porous and may absorb considerable formaldehyde vapor.

A metal ocular would not absorb any at all.

The best sterilization method that would be least irritating to the skin is to use a steam sterilizer. If one does not wish to install a steam sterilizer it is suggested that the instruments be soaked in a 1 per cent solution of saponated solution or creol for fifteen minutes, dipped into alcohol and then in sterile water. Another method is to dip the instruments into 1:1,000 Zephiran for fifteen minutes and then in sterile water. (Zephiran is an alkyl dimethyl benzyl ammonium chloride.)

If soap and scrubbing play a part it is suggested that the following formula be used in read or soap.

Sulfonated castor oil	2
Durol W A pure	2
Castor oil (undiluted)	1
	100

This makes a superlatted soap & detergent.

Dermatitis from rubber gloves is frequent among surgeons. It is caused most of the time by sensitivity to the accelerators and antioxidants, which are taken out of the glove by perspiration. Soaking the gloves for fifteen minutes in a 5 per cent solution of sodium carbonate followed by washing in water to remove the carbonate and then sterilizing by dry heat and wearing dry gloves, using plenty of powder, has in many instances made it possible for surgeons to wear rubber gloves when previously they have not been able to do so. The treatment of the gloves removes the excessive accelerators and antioxidants which otherwise would be removed by the perspiration.

Attention to vitamins or diet has not been proved to be of any value in cases such as that described.

Too much x-ray treatment may cause x-ray dermatitis and cancer.

VESICULAR ERUPTION AND CHIGGERS

To the Editor—We have in northeastern Texas a considerable number of insect bites which present a perplexing problem. The lesion at first is a small area of inflammation comparable to a mosquito bite and is most often seen on the lower extremities, but no portion of the body is exempt. It appears immediately after exposure and within eighteen to twenty-four hours becomes a vesicle ranging in size from 0.3 to 1 cm in diameter at the base and raised 0.1 to 0.5 cm. The entire lesion causes moderate itching, and a break in the wall with an escape of the contents causes extension of a reddened area to the surrounding portion. The lesion after an evacuation of the contents follows normal healing trends and becomes completely healed within ten days. My impression is that this lesion is a result of a dermatitis venenata combined with the bite of a chigger. If you can aid me to arrive at a diagnosis from my description and give me the best treatment for the condition I should appreciate it. Is there any insect which is called a blister bug? Lieutenant, M C, A U S

ANSWER—The chigger is a larval arachnid and not an insect. It most commonly invades the host by progressing upward from the feet until it meets an obstruction such as a garter, and there it usually attaches itself to the skin in the same manner as a tick. Its salivary secretion is an irritant and produces an intensely itching erythematous papule as large as a pea or a small coin, which does not appear, as a rule, until several hours after the bite has been inflicted. By that time most of the chiggers have become engorged and dropped off, so that they are difficult to find. The lesion is usually a papule, but it may be capped by a small pinhead size central vesicle, which may be hemorrhagic. The papule may persist for ten days or longer. No blister bug is known possibly that name might be applied to the chigger in some districts. Lesions of dermatitis venenata are not likely to resemble bites. They occur as irregular erythematovesicular patches and the vesicles may be large. Itching chigger bites may be relieved by a bath followed by the application of 70 per cent alcohol, after which the official boric acid ointment plus 1 to 2 per cent phenol and 0.2 per cent menthol may be applied, the excess wiped off and talc dusted over the surface. The bath should be repeated daily and the applications at least three times a day. Scratching must be avoided. Infestation with chiggers may be prevented by dusting powdered sulfur on the legs and ankles before going into the field.

CIRCUMSCRIBED PIGMENTED MACULES ON LIPS

To the Editor—A woman aged 35 has developed within the last three months in Florida a pigmented spot in the vermilion border of the lower lip quite close to the median line. The spot consists of fine, dark dots, probably corresponding to tips of papillae. Since the patient is a heavy cigaret smoker she attributed this spot to that. I should have thought so myself had I not had an exactly parallel case in a woman about the same age who developed such a dark spot in the same place without smoking at all. This woman was pregnant when the spot developed. Some years ago I saw a man with such a black spot in the lower lip. He used to smoke gold tipped cigarets and at that time I blamed that for it thinking of a local metal mark similar to argyrosis. Do you know anything about the significance and treatment of these spots, especially whether they have to be considered as precancerous conditions or not? There was neither inflammation nor keratosis in any of the cases.

Kurt Wiener, M D, Milwaukee

ANSWER—Circumscribed pigmented macules on the lips may be freckles, senile freckles, chloasma or superficial pigmented nevi. The differential diagnosis is difficult even after careful examination. The presence of other lesions on the face or elsewhere might be of help, but it is inferred from the query that none were found. Tobacco or gold tipped cigarets cannot be held responsible. Exposure to strong sunlight in the one case or the pregnancy in the second is a more likely cause. The only one of these four possibilities that might eventuate in carcinoma is the second. These, seen most often on the backs of the hands, sometimes become senile keratoses but may persist for many years without undergoing any such change. They should be protected from strong light, from exposure to the weather and from other irritation. The daily application of an emollient such as equal parts of wool fat and cold cream is of value.

POSSIBLE LYMPHOID TISSUE HYPERTROPHY IN NASOPHARYNX

To the Editor—A youth aged 17 had a tonsillectomy and an adenoidectomy at 4 years of age. In the early postoperative visits the surgeon introduced his finger into the nasopharynx "to break down the adenoid tissue." Shortly thereafter the child developed a "hawking." This has persisted up to this moment despite intermittent treatment with mild protein silver packs, nasal instillations and the use of vitamin A preparations. The "hawking" comes on fairly regularly one to two hours after the patient has fallen asleep, persists for three to four minutes and is loud enough to shake the rafters. He is not troubled during the rest of the night or at any time during the day. He is otherwise healthy and well developed. A laryngologist has called it "granular pharyngitis." What can you suggest by way of treatment? Captain, M C, A U S

ANSWER—A careful search for lymphoid elements in the nasopharynx should be undertaken in addition to a thorough check-up of the nose, accessory sinuses, oropharynx, larynx and pharynx.

The treatment will be based on the diagnosis. If hypertrophic lymphoid elements are found in the pharyngeal vault they can be removed by surgical measures or, if solitary follicles are noted on the postpharyngeal wall, electrocoagulation will prove the quickest method of dealing with them. Smaller lymphoid structures on the vault or in and around Rosenmüller's fossae might require the aid of a radiologist thoroughly grounded in the principles of applying radium or x-rays in accurate dosage and at proper intervals. Recent advances along these lines have been brought forth by S J Crowe of Baltimore and others.

Lymphoid hypertrophy in the laryngopharynx might be present and should be dealt with by surgery or electrocoagulation.

Septal irregularities, spurs, ridges, hypertrophies and hyperplasias, when found, require surgical correction in order to establish good intranasal mechanics.

Catarrhal and/or suppurative states in the nasal accessory sinuses should be treated by conservative means to promote aeration and drainage, for many cases of pharyngitis have their cause in a focus higher up and by gravitation of infected material from any group of sinuses down the nasopharynx reinfected and reirritate lymphoid structures in the naso-oropharynx and laryngopharynx, evoking some of the symptoms described in the query. Nasal shrinkage, instillations, applications, packs, irrigations and displacement therapy after the method of A W Proetz of St Louis will aid in the functional improvement of the nose and nasal accessory sinuses, and application of astrinents to the pharynx will help "burn down" the lymphoid hypertrophies.

All measures calculated to establish the highest degree of health should be diligently carried out. Metabolic faults and alterations in the blood, glandular and other systems should be corrected as quickly as possible so that a balanced state of bodily economy may be maintained and retained.

PHYSIOLOGIC DISTURBANCES ACCOMPANYING SHOCK

To the Editor—In connection with the syndrome of traumatic shock, is there a difference in hemoconcentration between peripheral capillary blood and venous blood? In other words, would hematocrit and red blood count and hemoglobin determinations vary between these two sources of blood in a case of this syndrome? Would you kindly refer me to recent sources where I might obtain descriptions of the physiology and treatment of this condition? M D, New York

ANSWER—In the early stages of traumatic or secondary shock, before the systolic blood pressure has declined below 80 mm, there is little difference between the concentration of the blood in the capillaries and that in the veins and arteries. In later stages, stasis of blood develops in varying degrees in the capillary bed in different systemic areas. In such areas the concentration of the blood is greater than in the circulating blood, either venous or arterial.

The literature bearing on the physiologic disturbances which accompany shock has been reviewed and summarized in *Shock: Its Dynamics, Occurrence and Management* by V H Moon (Philadelphia, Lea & Febiger, 1942). The same work deals with clinical problems and management. The National Research Council has sponsored a military surgical manual on Burns, Shock, Wound Healing and Vascular Injuries, published by W B Saunders, Philadelphia, 1943.

PILONIDAL CYST AND CANCER

To the Editor—In the Jan 18, 1941 issue of The Journal there is a query with regard to pilonidal cysts and cancer submitted by Dr E V Andrew of Moquoketa, Iowa. The answer submitted stated that no case had been found in the literature of cancer developing in a pilonidal cyst. This makes me feel a little guilty, because several years ago at St Luke's Hospital I removed an innocent looking pilonidal cyst from a young man, and the pathologic report came back as squamous carcinoma. I have meant to report this case but just never got around to it. Inidentally, although the operation was done on May 9, 1937, the man is still well in every respect.

THORACIC AND LUMBOSACRAL CORD INJURIES

A STUDY OF FORTY CASES

DONALD MUNRO, M.D.

Neurosurgeon in Chief and Head of the Department of
Neurosurgery, Boston City Hospital
BOSTON

Injuries to the thoracic and lumbosacral cord have not been granted the study that their importance justifies. If, for example, it had been generally recognized that the mortality of this group of injuries as compared with that of cervical cord injuries is roughly as 6 is to 4½ and that it is this class that includes all the surviving patients with transected cords with their attendant invalidism and problems of rehabilitation, greater attention would have been paid these injuries not only by neurosurgeons but by general and orthopedic surgeons as well. Grinker¹ in his textbook of neurology devotes only ten pages to the entire discussion of injuries to the spinal column and cord and states that (p 182) "treatment of cord injuries is extremely hopeless." Frazier and Allen² note that severe injuries to the thoracic spine predicate the application of tremendous violence (p 368) but do not otherwise differentiate thoracic and lumbosacral cord injuries from those above and below. Homans³ does not devote more than seven pages to all injuries of the spinal cord. He does make a detailed distinction, however, between injuries in the cervical and in the thoracolumbar regions (p 715 et seq). In 1940 Elsberg⁴ writing in Brock,⁵ devotes only forty-eight pages to all cord injuries, of which one is devoted to thoracolumbar injuries, and in 1941 in his own book he⁵ makes no such distinction and covers the whole subject in forty pages.

Any discussion about any level of spinal cord injuries should always be based on two fundamental concepts. These are (1) that spinal cord injuries are entirely different from spinal column injuries without cord involvement and (2) that any significant spinal cord injury is always accompanied by spinal shock and its effects. The first of these two concepts is self explanatory but almost always ignored. One has only to refer to the literature to discover that many authors draw conclusions as to the diagnosis, treatment and prognosis of a neurologic injury from a mixed series of both cord

and vertebral column injuries. This failure to distinguish between strictly orthopedic and strictly neurosurgical matters has, among other things, held back the understanding and treatment of pressure and bed sores. When a spinal cord injury is present, any associated bone injury is secondary and of relatively little importance. Under such circumstances diagnosis, therapy and prognosis are all primarily problems of the cord injury, and the bone damage is subordinate from every point of view. Only when there is a back injury in which the spinal cord has been undamaged do the bony structures and any changes in them properly assume first place in the consideration of the case. Until this is generally recognized and acted on but little improvement can be expected in the functional end results of spinal cord injuries.

This report deals only with injuries to that part of the spinal cord which is enclosed within the confines of the twelve thoracic vertebrae. It thus includes the thoracolumbar and sacral portions of the cord and the conus medullaris as well as the twelve thoracic vertebrae. Neither the cervical cord nor the cauda equina is included except in an occasional case in which this involvement was secondary and traceable to either a spread upward of hematomyelia or to the injury of multiple vertebrae in the dorsolumbar spine. There are 40 patients in the series. Seventeen have survived and been followed to an end result in 13 instances for varying periods from seven months to nine and one-half years. Twenty-three patients died—a case mortality of 57.5 per cent. Autopsies were obtained and the spinal cords studied in 11 instances, or about one half of the deaths.

SPINAL SHOCK

Spinal shock is a constant accompaniment of all significant spinal cord injuries. It is recognized by its effects and is known to occur at once after the infliction of the injury and to last for periods varying from a few hours to months. It has nothing to do with surgical shock. As the result of its presence all reflex activity below the level of the injury becomes chaotic, unpredictably variable and devoid of any diagnostic or prognostic significance. It probably also has a like effect on other motor activity in the same area although this is less certain. The reflexes involved include not only the somatic variety such as the knee jerk but also the less easily elicited and often forgotten splanchnic reflexes. The latter control the activity of the bladder and bowel and the response to local pressure on the part of the blood vessels in the skin. The deleterious effect of spinal shock is greatest on those reflexes mediated by the spinal segments immediately below the level of injury and decreases proportionately as lower segments are reached. Thus in cervical and upper thoracic injuries a minimal effect is produced. As the location of the injury descends however bladder difficulties and

bed sores, for example, become increasingly common because of the closer approximation of the segments controlling these reflexes to the level of injury

NATURE OF THE ACCIDENT

The commonest accident leading to injury in this series was a fall from a height. This occurred 21 times or in about one half of the cases. The height varied from five stories to 10 feet. One fall was suicidal and in 2 the patient was thrown off a roof and an electric light pole respectively by the shock following contact with live wires. Sixteen of these patients died. Automobile accidents were the next most common. There were also 4 gunshot wounds, 2 of them fatal, 2 patients were crushed, 2 were dragged, 1 beneath an automobile and 1 beneath a train, 1 was stabbed with an ice pick, and there was no certain proof of the presence or absence of an accident in the 2 other cases. The last 2 and the 2 patients who were crushed survived whereas the patient with a stab wound and the 2 who were dragged died.

THE BONY INJURY

Although of less importance than the cord injury it is more convenient to deal with the bony injury first. In 3 cases there was no demonstrable bony injury. The cord damages in these instances were a single intramedullary hemorrhage, compression from local calcification and degeneration of the ligamentum flavum and transection from a stab wound. There were 4 bullet wounds. X-ray examination was not carried out in these and 1 other case. Of the 32 other patients with demonstrated bone injury 10 had a dislocation associated with the fracture or fractures.

Fig 1—Anterior (A), lateral (B) and posterior (C) dislocations of the vertebrae. The distribution of the upper level of spinal cord injury in 40 cases of thoracolumbar cord injuries.

It may be worth while at this point to call attention to the fact that a true posterior dislocation has actually occurred only once in my series of 216 spinal cord injuries. It has been diagnosed more often but, except for this one occasion always wrongly. Figure 1 emphasizes the difference between the anterior and the true posterior dislocation and depicts the only arrangement of the bones that justifies the diagnosis of a posterior dislocation. This is not without its importance. In at least 2 of my cases an incorrect diagnosis of posterior dislocation made by the x-ray department has led inexperienced surgeons to attempt reduction by flexion despite the fact that, at most, it is indicated only as a preliminary to extension in cervical injuries. Augmentation of the cord injury occurred in 1 case, and the production of cord damage when it had not been present before the attempted "reduction" followed in the other. Sixteen patients in this series had fractures of more than one vertebra—usually two but occasionally three adjacent ones. If the thoracic column is divided into three

parts (table 1) it is apparent that the first four vertebrae were fractured in 5 instances and that there was only 1 case in which an associated dislocation occurred. The fifth, sixth, seventh and eighth vertebrae were fractured 10 times with 3 dislocations, and the last four vertebrae were fractured 15 times with 6 dislocations.

In 1 other case there is certain evidence of an upper thoracic transection, but the bone injury as far as x-ray evidence is concerned is restricted to the sixth and seventh cervical vertebrae. The lumbar spine could not be shown to be damaged in any of these cases. From this series it would appear that the lower thoracic vertebrae were more liable to fracture than the upper and that the lower the fracture the more probable is the presence of an associated dislocation.

PATHOLOGY OF CORD INJURY

Nineteen of the 40 patients had transections of their spinal cords. Seven of these recovered. This is in striking contrast to the cervical injuries in which there were only 13 transections with 1 recovery out of 100 cases seen during the same period of time. The findings were verified at operation or autopsy or both in every case except 5, and in these 5 the clinical manifestations

were typical. One of the patients whose injury was verified by all three methods had two transections. He had been transported 15 miles in the back seat of a touring car after falling from a roof. There were 5 contusions of the cord, 3 of which were verified, and 5 compressions all verified by either operation or

Fig. 2—Patient recumbent with upper thoracic transection and paraplegia in flexion and adduction with a mass reflex.

autopsy or both. In 1 of these the compressing agent was an extradural clot. Six patients had hematomyelia and 2 edema. These diagnoses were impossible of verification except by their clinical course. In 2 cases the injury could not be certainly determined and 1 had subarachnoidal hemorrhage. The compression in 1 case was caused by the calcified ligamentum flavum previously mentioned.

The uppermost level of the cord injury is of some interest (table 2). All 12 thoracic, 1 lumbar and 1 sacral segment as well as the conus were represented in the series. If these 15 levels are divided into thirds and the living and dead patients plotted separately, it appears that of 14 patients with lesions involving the first five segments 8 survived and 6 died. So also with the last five levels (that is the eleventh and twelfth thoracic, the first lumbar, the second sacral and the conus), 5 of 10 patients survived. In contradistinction to this when the injury involves the middle thoracic segments (that is the sixth through the tenth thoracic) 12 of 13 patients died. This suggests that injuries to the middle segments of the thoracic and lumbosacral cord are more often fatal than to the regions above and below this area. It is probable on this evidence that although the bony injury is most severe at the level of the four lower thoracic vertebrae the cord injury is not only most severe but is most often fatal in the region of the middle thoracic vertebrae.

DIAGNOSIS

I am convinced that the best one can do in making a diagnosis at or close to the time of the receipt of a cord injury is to determine the upper level of the damage by a sensory examination. Otherwise the physician is limited to a decision as to whether the injury is of the type that does or does not cause a block of the cerebrospinal fluid. The bone damage also can only be approximated. The lesions that cause a block of the flow of cerebrospinal fluid are edema with or without hematomyelia, contusion, compression and concussion of the cord. The compression may be caused by a meningeal clot, a fragment of fractured bone, crushing of the body or dislocation of a vertebra. Concussion is associated only with bullet wounds of the bony wall of the canal. Lesions that do not cause a block of the

flow of cerebrospinal fluid are hematomyelia without edema, anatomic transection and rarely an overlapping tear in the dura and arachnoid with an undetermined amount of cord injury. This last permits cerebrospinal fluid to be diverted to the extradural or subdural space during lumbar puncture and thus prevents filling of the subarachnoid space below the point of injury. Such findings may lead to the diagnosis of cerebrospinal fluid block when none is actually present. Conditions that do not produce block may be present as a complication of any of those which do cause a block and, of course, be unrecognizable, but the reverse is never true. Final differentiation between individual pathologic entities within these two classifications has to await the final outcome of the case and may not be possible for months or even years. Even then it may be impossible unless major sepsis is not present the patient is not suffering from hypoproteinemia the bladder has reached a satisfactory functional end point and proper physical therapy and splinting have been practiced.

Diagnostic and prognostic conclusions based on the onset, type and extent of motor or reflex disability are never justified. Even observations made of the exposed cord at operation are not necessarily accurate or dependable. This is particularly true when the cord looks as though it had sustained little or no damage as far as its surface goes. Because the vascular supply to the cord is minimal and so constructed as to produce a bottleneck⁶ in both the arterial and the venous channels its tissue is particularly vulnerable should damage to the arteries or venous thrombosis occur. Cells that would not have sustained lethal damage in any other tissues will not recover, and a spreading myelomalacia may develop in the presence of damage to a single artery or of thrombosis of a single vein at certain critical levels.

Fig. 3—Same patient as in figure 2, showing him seated.

on account of the lack of collateral circulation. A detailed study of the cases in this series has demonstrated that in 20 the immediate and final diagnoses agreed and in 15 they did not agree. Agreement and disagreement could not be determined in 5. The agree-

ments occurred in 8 cases of transection, 4 of compression, 1 of contusion, 1 of edema, 5 of hematomyelia and 1 of subarachnoid hemorrhage. The disagreements were as follows: 6 contusions, 5 compressions and 2 concussions proved to be transections, 1 compression turned out to be a contusion and 1 case of hematomyelia

Fig 4—Patient with upper thoracic transection, ambulatory with the aid of braces and crutches. A, upright, B, seated.

to be thrombotic myelomalacia. The immediate diagnoses in 22 of these instances were made after visualization of the cord at operation and the final diagnoses either by study of the cord at autopsy or after adequate follow-up. The metamorphoses occurred because of the progressive degeneration that took place in the cord after the diagnosis was first made.

I have already noted that diagnostic and prognostic conclusions based on the onset, type and extent of motor and reflex disability are never justified. I believe that recognition of this fact is extremely important. It comes about because of the changes wrought by spinal shock. Twenty of these cases could be studied in detail from this point of view. The development of motor paralysis below the level of the injury and immediately following the accident in relation to the first diagnosis was as follows: There were 8 cases of immediate transection in which the onset of paralysis followed the injury at once and 1 in which it was delayed. All patients had a mass reflex and no return of voluntary motion at their discharge. One had a completely transected cord and a torn dura at operation. There were 6 cases first diagnosed as contusion of the cord in which the injury was followed at once by complete paralysis and 1 in which paralysis was delayed. The diagnosis was made at operation in every case. In 3, free macerated cord tissue was found floating in the cerebrospinal fluid. In 2 other cases the cord was described as being swollen and not pulsating. Improvement in the paralysis did not occur in any of these cases. There were 12 cases in which a first diagnosis was compression of the cord, the diagnosis being made at operation in every case except 2. All patients had immediate complete paralysis; nevertheless 1 patient is well and free from symptoms nine and one-half years later.

There was 1 patient with edema and 3 with hematomyelia who were paralyzed at once after the injury and 3 in whom the onset of paralysis was delayed, all of whom either completely or largely recovered before discharge. Finally there were 2 patients with concussion, 1 of whom has had no improvement in eight and one-half years. The other is still in the ward. The patient with subarachnoid hemorrhage had little paralysis at any time. There were 2 others in whom the time of onset of paralysis was uncertain. Thus 4 patients with an immediate onset of paralysis completely recovered, and in 11 others the end result was more serious than the original diagnosis suggested. Certainly the occurrence of motor paralysis, which develops at once after receipt of injury and is supposed to be a pathognomonic symptom of transection of the spinal cord, cannot reasonably be considered to be such a symptom when it is known to be wrong in one direction 11 per cent and in the other 29 per cent of the time.

The demonstration of the presence or absence of a block of the flow of cerebrospinal fluid is made by a study of the total protein content of the fluid below the block and the performance of a fractional Queckenstedt test. Evidence of block by increase in total protein will frequently appear before and will always outlast the evidence of dynamic block. The fractional Queckenstedt test is best done by compressing the jugular veins, not by hand but by inflation and deflation of a blood pressure apparatus cuff wrapped around the patient's neck. Observations on the intracranial pressure are made and recorded with every increase of 10 mm of pressure in the cuff from 0 to 40 and similarly with every 10 mm decrease from 40 to 0. Partial dynamic blocks are recognizable by this method when every other method fails. As has been pointed out, if a block is present the patient is suffering from either edema with or without hematomyelia, contusion, compression or concussion of the cord. If a block is absent the patient is suffering from either hematomyelia without edema or an anatomic transection. The only source of diagnostic error lies in the rare possibility of the patient having coincident tears in his dura and arachnoid and presenting signs that superficially appear to indicate a

Fig 5—Same patient as shown in figure 2 after operative abolition of the motor component of the mass reflex, showing him recumbent.

block when there is actually none present. Further diagnostic differentiation is unjustified and impossible until the pathologic condition has reached an end point.

TREATMENT

Certain general principles of treatment must be adhered to if the end results that the patient has a right to expect are to be obtained. Every patient with a spinal cord injury should have his bladder emptied and

an indwelling catheter fastened in place at the earliest possible moment. It is impossible to do this too soon. As soon afterward as it can be done this catheter should be attached to a tidal drainage apparatus properly adjusted by cystometry to the needs of the individual bladder. Simultaneously with this the patient should

Fig 6—Same patient as shown in figure 5 only in a wheel chair

be treated for surgical shock if and when it is present. Both should precede all but the most superficial diagnostic measures. The demonstration of the presence or absence of a block should always follow this procedure and come before all other measures. Splints, no matter what their material, that are fixed in relation to the patient must never be used in spinal cord injuries and especially in the thoracic and lumbosacral injuries. In particular the application of plaster of paris is contraindicated regardless of the amount of padding used. So too are rubber and other rings or doughnuts, Bradford or other frames and water or air mattresses. Metal frames for hyperextension or any methods which aim to accomplish rapid hyperextension are also contraindicated. Sufficient protein must be given to these patients in their diet or by transfusions or other means to maintain their serum protein at 6.0 or better. Their salt intake must usually be increased also and they should be started at once on large amounts of all the vitamins. While the patient remains on tidal drainage his fluid intake should never be allowed to fall below 4,000 cc in twenty-four hours for an adult. Care must be taken to keep the bowels open and prevent the development of fecal impactions. All patients must be moved off their back and onto one or the other side every two hours day and night, during their stay in bed. They should never be allowed to lie in a wet bed for even as little time as fifteen minutes. These are all general measures that apply to all patients with spinal cord injuries until such time as they have reached anatomic and functional end results regardless of the diagnosis. Other procedures will depend on the presence or absence of a positive Queckenstedt test. This must be determined in every case without exception and should be carried out after the patient is out of surgical shock and on tidal drainage.

If there is no block there is no need for operation, and x-ray examinations can and should be postponed for four to six weeks. The patient should be placed on a sponge rubber mattress on top of a hair mattress and bed boards, with the bed made up in the usual manner, his feet supported at right angles and with the bed clothes held off of them by a cradle, and his knees held on pillows in slight flexion. If necessary, the spine should be hyperextended by the method to be described later. Physical therapy can be started if the patient's muscles are not hypertonic. If they are, it is harmful and contraindicated. At the end of eight weeks, if there is adequate bone repair as evidenced by x-ray examination, he may be got out of bed if he wears a steel Taylor back brace. By this time those patients who have had a hematomyelia should be about to regain or have actually regained normal control of the bladder and bowel. They should be fitted for and provided with the necessary splints to make them ambulatory and to provide them with a maximum of functional activity. A constant x-ray check should be made of their bone injury until such time as the physician is certain that it is completely healed and capable of bearing the body weight without the aid of a splint. If the bone condition regresses the patient may have to be put back to bed or rarely fitted with a plaster or castex jacket.

Patients in this group who have a transection will prove the most difficult to handle. The same principles apply but the details of application are more time consuming and difficult of control. A defeatist attitude on the part of everybody concerned must be avoided at all costs. Nothing less than an active self-supporting wheel chair life is to be considered for a moment as an end result, and ambulatory activity with the aid of splints should be the eventual goal if at all possible. Time must not be allowed to be a factor, and the physician, the patient and his relatives should all constantly be striving toward that end. It is these patients who make up the bulk of those with thoracic and lumbosacral cord injuries. It is they who are most apt to develop pressure sores and if their two hourly turning is neglected or if they are permitted to lie in a wet bed for as short a time as fifteen minutes, those pressure sores which are already present will turn into bed sores and other new pressure sores be added. As these patients

Fig 7—Hyperextension of the thoracic spine by means of a Blauvelt roll beneath the mattress and on top of bed boards

get better a mass reflex develops and paraplegia in flexion and adduction starts. To complicate the situation further the tidal drainage apparatus becomes inefficient because of the irregular bladder responses to the abnormally spreading motor impulses of the mass reflex. Patients cannot be turned or got out of bed because of the position of their legs (Fig 2). The cry

fact that they are improving neurologically leads to complications inherent in that improvement. Traction, splinting and physical therapy not only do no good but are actually harmful in such cases. Such procedures either act as sensory stimuli to the mass reflexes and set up more flexor contractions or cause pressure and

possible to mobilize these and other similar patients even to the point of fitting them with ambulatory splints. While still only in the experimental stage, it promises more than any previous approach.

THE QUESTION OF OPERATION

Patients on whom the Queckenstedt test is positive pose the question of whether or not this block should be relieved by a decompressive laminectomy. This is not to be undertaken lightly. My cervical cases showed a drop of 30 per cent in mortality after laminectomies were abandoned in cases in which there was a block. On the other hand the comparison of cervical with thoracic or lumbosacral cord injuries is not quite fair because of the complicating respiratory difficulties that are inherent in the cervical cases and not present in the others. Furthermore, a block implies pressure on the surface of the cord at some point. Unless this is relieved at the earliest possible moment spinal cord damage that would not otherwise have been present will occur. Before a decision as to operability can be made, information must be obtained as to whether the block is caused by bony pressure from the outside or swelling of the cord itself. An x-ray examination is essential at this time. This should include a lateral stereoscopic view for the middle and lower and an oblique stereoscopic view for the upper thoracic vertebrae. If the canal is distorted by a dislocation or angled by a crush fracture of a vertebral body, the patient should be hyperextended (fig 7) by having a roll of blankets placed beneath the sponge rubber and regular mattresses and on top of the bed boards opposite the kyphosis. The roll should be increased in size daily and its efficacy checked by a daily Queckenstedt test. If the block is still present

Fig 8—Pressure sore

later bed sores in the extremities that are splinted. Plaster of paris is particularly pernicious in these cases.

Not all patients with transections are like this, but those who are not probably have not a complete but a partial transection. My experience would indicate that even a minimal retention of neural connections between the cord segments above and below the injury so modifies the mass reflex that paraplegia in flexion will not occur, although it does appear that such patients still have an abnormally active bladder and one that is very difficult to control. Despite that, however, patients with partial transection can be made ambulatory in many instances (fig 4) and if not can lead active wheel chair lives, as evidenced by a patient in this series who has done so for eight and one-half years.

I am not yet sure how best to handle the late phases of the problem of patients with complete transections, particularly the bladder difficulty, which is the most important part. Certainly tidal drainage does not work, and it seems better to approach the problem by abolishing the mass reflex rather than by trying to treat the bladder. I have done this now in 4 instances. All the anterior spinal roots from the twelfth dorsal to the first sacral inclusive are cut intraspinally on both sides. Since the leg muscles become flaccid, the flexion deformities are relieved and the spread of the motor responses to minimal sensory stimuli are abolished (figs 5 and 6). In this way the bladder is no longer stimulated by contraction of the abdominal muscles, and tidal drainage can again control the urinary outflow. Moreover, because the patients are kept dry, the skin of their backs and hips is healthier and pressure and bed sores heal. I believe that eventually it will be

Fig 9—Bed sore

at the end of four to seven days a decompressive laminectomy should be done. I have found that this method is highly efficient in cases of block caused by bony compression and practically eliminates the need for operation in all but the lateral dislocations. These have had to be operated on. If there is no dislocation or kyphosis visible by x-ray examination to account for the

block, dehydration and moderate hyperextension should be tried for three to five days. If this therapy has been unsuccessful in relieving the block in that time and provided there are no complications such as a hemo-pneumothorax, laminectomy should be performed. No attempt should be made at operation to reduce any

Fig 10—Healing bed sore

dislocation that may be present and as little as possible should be done beyond opening the dura, removing loose fragments of bone and being certain that the flow of cerebrospinal fluid past the point of block is unimpeded. The cord should never be incised except in the rare instances of a single intramedullary clot. If other hemorrhages or one of the cysts that follow concussion are found and have to be dealt with or emptied this may be done by puncturing the area with a hypodermic needle and evacuating it with the aid of a syringe. The dura should be left open and the rest of the wound closed in layers without drainage. Bullet wounds, whether causing a compound fracture with cord laceration or concussion of the cord by passage of the bullet through some part of the bony wall of the canal without contact with it or the meninges, should all be debrided as soon as the patient's general condition and complications permit. With the block relieved, the care of the cord injury and the patient is the same as that outlined in the absence of a block.

COMPLICATIONS

One of the first and most important complications of injuries to the thoracic spine is the presence of a hemo-pneumothorax. I am not aware that it has been mentioned previously as such in the literature and I know that I have overlooked it myself in the past. Its presence causes much respiratory embarrassment especially when the patient is shifted from back to side and may produce a mediastinal shift. On physical examination it causes signs that are usually interpreted as pneumonia and a correct diagnosis is often impossible except with the aid of a thoracentesis. I have now made such a procedure routine whenever pneumonia is diagnosed and whenever there is respiratory embarrassment, fractures of the ribs or a major dislocation of the vertebrae present in thoracic and lumbosacral cord injuries. When found the removal of the pleural fluid will often prove life saving. Six to ten daily thoracenteses will usually be necessary to return the pleural cavity to normal. If the bullet wounds are excluded this condition was proved to be present in 6 of the 38 patients in this series or 16.5 per cent. I have reason to believe that others were missed in the earlier patients.

PRESSURE AND BED SORES

Pressure and bed sores occur in a high percentage of patients with thoracic and lumbosacral cord injuries. It is almost impossible to avoid pressure sores (fig 8) while the patient is bedridden. The unforgivable sin is either to allow the pressure sores to go on to the point of becoming bed sores (fig 9) or to fail to heal either or both by the time the patient is out of bed. I have described the points of differentiation treatment and usual sites of occurrence of these complications in an earlier paper. I will only repeat the conclusions drawn then and confirmed by further experience. Pressure sores always antedate bed sores. The former develop because of prolonged weight bearing on bony prominences and of maceration of the horny layers of the skin. The latter follow because of interference with the skin-vascular reflexes. The best treatment of bed sores is prevention. This is accomplished (fig 10) by keep-

Fig 11—The tidal drainage apparatus with a built-in sphygmometer

ing the patient constantly dry, turning him every two hours as long as he is bedridden, maintaining his serum protein at 60 or above and his blood chlorides at a normal level and refraining from doing any surgery to the sore and dressing it only once a day and only with a dry sterile dressing.

THE BLADDER

Successful care of the bladder can be carried out only by the proper use of tidal drainage. The apparatus (fig 11) has been greatly simplified and is now constructed in such a way as to include a built-in cystometer. There is, therefore, no excuse for a failure

Fig 12—Genitourinary system removed post mortem from 2 patients who had each been treated with tidal drainage constantly for one and one half years

to make enough cystometric examinations to assure proper working of the tidal drainage. I have covered this problem in detail elsewhere.⁸ I should like to emphasize, however, that today patients who have sustained spinal cord injuries may expect certain genitourinary end results. Failure to provide these end results is traceable in every case not to the injury but rather to the physician who has been caring for the injury. These end results are as follows: 1. With a destructive lesion of the sacral segments the outcome will be a useless, hypertrophied bladder that leaks constantly and that cannot be controlled by any mechanical means available at present. 2. With a transection of the cord at any level the result will be a reflex bladder with a capacity of 150 to 250 cc which empties only when its capacity is reached and not otherwise. If tidal drainage is used only at night and an inlying catheter is consequently necessary, the patient will have a bacteriuria but should not have a clinical pyelitis, ureteritis or cystitis. 3. Every other patient who has sustained a spinal cord injury should have a normal genitourinary apparatus with sterile urine and normal function at the time of his discharge from the hospital.

END RESULTS

Twenty-three of the 40 patients in this series died in the hospital. This is a case mortality of 57.5 per cent. The causes of death are interesting and significant (table 3). Only 2 patients died of surgical shock—one after seven hours and the other at the end of three days. One died from multiple injuries at the end of four days and 2 of circulatory failure after eight and nineteen days respectively. These 5 patients (22 per cent) were the only ones who died because of the immediate direct result of the trauma. This figure should be compared with the 40 out of 46 (82.5 per cent) similar cervical deaths. There were 2 patients who certainly and 1 who

probably died from hypoproteinemia, two and one-half, eleven and fifteen months after injury. These deaths would not have occurred today and were preventable.

Five patients died of intercurrent diseases: 1 at the end of two years and three months from peritonitis caused by a ruptured enterostomy wound, 2 from pulmonary emboli at the end of seven days and eleven months respectively, and 1 each from a decompensated heart and a coronary occlusion after thirteen and twenty-four days respectively.

Ten patients (43.5 per cent) died of sepsis. A comparable figure in the cervical group is 4 out of 46, or 8.7 per cent. Only 2 of these 10 patients had meningitis—one because a laminectomy wound became infected and the other because a gunshot wound was not debrided in another clinic and the patient was then turned over to us to die. Four patients died from sepsis of the genitourinary tract. In 2 of these the sepsis followed instrumental perforation of the urethra and operative perforation of the bladder. The first was done with a styleted catheter and the second with a lithotrite. Both occurred because the genitourinary surgeon was without his usual guide post of pain and did not realize the limitations that this set on his freedom of movement. Another died because the tidal drainage apparatus was not operated correctly, and the last died before any

of this work had been started. Today death from genitourinary sepsis would not be countenanced in my service. Regardless of other causes of death, kidneys, ureters and bladders removed at autopsy should show no more than a very superficial cystitis (fig 12). Three patients died from sepsis traceable to a bed sore and 1 from a thrombotic myelomalacia that originated in a

8. Munro, Donald. Tidal Drainage and Cystometry in the Treatment of Sepsis Associated with Spinal Cord Injuries. *New England J Med* 229: 614 (July 1) 1943.

femoral phlebitis which developed during treatment of a contusion of the back. Control of bed sores and the sepsis arising from them is still far from ideal and tremendously difficult to deal with. House officers and nurses cannot be made to believe that failure to move the patient on schedule, failure to change a wet bed within fifteen minutes of its having become wet and failure to maintain an adequate level of serum protein cause pressure and bed sores and prevent bed sores from healing until the patient has proved it to their satisfaction by dying. Then, having learned their lesson by bitter experience, these trained attendants are transferred to another ward or leave the hospital, and the educational process has to be repeated with another untrained group. Constant attention to these apparently trivial details is consequently imperative on the part of the visiting staff if it has any desire to lower the mortality and shorten the hospital stay of these patients.

Seventeen patients survived (table 4). All but 4 have been followed to an end point. End results have been listed as failure, satisfactory, and well. The

† Died of lobar pneumonia at the end of that time.

patients whose end results are classed as satisfactory are active and leading either a normal full or a normal wheel chair life. Those classed as well are doing this and earning their living in addition. Of the 4 patients who have not been followed, 3 are in the hospital under treatment. The other has been lost sight of but his condition was considered satisfactory at the time of his discharge at the end of five months. There were 2 failures. 1 patient died at home of genitourinary sepsis 2 years, and 1 is still bedridden at another public institution one and one-half years after their respective injuries. The condition of 5 was satisfactory. One of these died of intercurrent pneumonia at the end of two years. The others were alive three years, two years, one year and six months and eight months after discharge from the hospital. Six are well, 1 of whom is caring for a family of five eight and one-half years after discharge. She leads a wheel chair life but cooks, sews and is active socially. She is and has been during that time constantly on tidal drainage, which she cares for herself. The others are all working seven months and four, seven, seven and one-half and nine and one-half years after injury.

TUBERCULOSIS CASE FINDING BY GENERAL HOSPITALS

WILLIAM G. CHILDRESS, MD

A. G. DEBBIE, MD

AND

E. L. HARMON, MD

VALHALLA, N. Y.

Examination of admissions to general hospitals by routine x-ray or fluoroscopic examination of the chest has not been widely utilized as a source of tuberculosis case finding.

Our purpose in this paper is to report the results of a tuberculosis case finding demonstration at Grasslands Hospital extending over a period of eighteen months dating from July 1, 1941 to Jan. 1, 1943. The program was sponsored and financed jointly by Grasslands Hospital, the Westchester County Tuberculosis and Public Health Association, Inc., and the Westchester County Department of Health.

The study was to demonstrate the yield of tuberculosis that may be expected by routine x-ray or fluoroscopic chest examination of patients admitted to the hospital or its outpatient department who were not suspected of having pulmonary disease and would not customarily be examined in this way. All admissions to the chest services and those with known or suspected pulmonary or heart disease who would have received an x-ray or fluoroscopic examination of the chest as a usual procedure have been omitted from the study.

Of a total of 9,693 individuals admitted to the hospital or its outpatient department 7,187, or approximately 74 per cent, were included in the study. Those not included represent admissions to the chest services or those with expected heart or lung disease and a small number of whom examination was not practical. Those were recalcitrants or moribund patients and a few admissions to the psychiatric and contagious departments.

Clinic admissions were first examined by the fluoroscope and, when evidence of disease was present, roentgenograms were also taken. House admissions received routine roentgenograms of the chest on the standard 14 by 17 inch film. There were 2,471 examined by fluoroscopy and 4,716 by x-rays. The number of roentgenograms includes 263 patients referred after fluoroscopic examination.

Fluoroscopies were done by physicians of the tuberculosis and x-ray departments. X-ray films were interpreted by the roentgenologist and, when evidence of pulmonary disease exclusive of healed primary tuberculosis existed, the physician in charge of the tuberculosis division collaborated in the interpretation and classification.

Special efforts were not made to compare the accuracy of the two techniques of examination, but in computing the results it was found that the number of active or questionably active in the two groups was practically identical. Results from the two techniques have therefore been combined in the table, which represents the total number of examinations, age groups, sex and dynamic status of tuberculosis found.

Of those examined 80 per cent were native born and 20 per cent foreign born. Seventy-nine per cent were white and approximately 21 per cent colored.

There were 8 individuals of the yellow race. Of those examined, 3,985 were males and 3,202 were females.

With few exceptions, physical examination by members of the tuberculosis staff was done on all patients with reinfection disease while in the hospital or subsequently in the chest clinic. When this was not possible, reports were sent to the referring physicians and the health departments in the county. All reinfection tuberculosis was reported even if not considered to be active.

The apparently healed primary lesions were obvious calcifications, and no attempt was made to determine primary infection without positive evidence. Where massive calcification was present in the mediastinal and bronchopulmonary nodes, with sparse deposits of calcium or light patchy or linear fibrosis in the lung without evidence of activity, these were classified into minimal apparently healed in order that they might be reported for follow-up and contact examination. It is likely that some of these are of the primary infection type.

surveys in various sections of the country. Screening of these groups should be preceded by tuberculin testing. In addition to the tuberculosis discovered there were 23 individuals with significant nontuberculous lung or heart lesions.

In 1932 Mills and Stewart¹ examined 353 patients admitted to the Swedish Hospital in Minneapolis and found that 14 per cent of the total had reinfection tuberculosis. Their studies were made by first tuberculin testing and then by chest x-ray examination of the positive reactors. In 1935 F. J. Hodges² of the University of Michigan conducted a chest x-ray survey of 1,101 patients admitted consecutively either to the University Hospital or to its outpatient clinic during a period of fourteen days and found "significant chest disease unrecognizable by other methods and often totally unexpected on the basis of chief complaint and history" in 13 per cent.

In 1935 Pohle, Paul and Oatway³ of the Wisconsin General Hospital took chest x-ray films of 1,417 patients admitted during a three month period. Patients with

Evidence of manifest tuberculosis was present in 290, or 4 per cent, and of these 201, or 28 per cent, showed evidence of reinfection disease, 42, or approximately 0.6 per cent of the total 7,187, were classified as active or questionably active, 3 of these were active primaries. Activity was established in 25 of the 42, or approximately 0.35 per cent of the total number examined. This group was classified after correlating the hospital or clinic record with the x-ray findings.

A breakdown of active and questionably active disease shows the larger number to be in men above 30 years of age. The ratio of males to females examined in these age groups was approximately 3.2, ratio of yield about 7:1.

We have used active and questionably active classifications to avoid the term "significant" and to mean that clinical activity was proved or could not be excluded.

As a result of the survey, 27 patients were admitted to the tuberculosis division of the hospital and admission was advised for 7 others who refused. The low yield in the younger age groups is what would be expected and has been amply demonstrated in school

history, symptoms or physical signs of a pathologic condition of the chest were excluded. About 3 per cent of the total number receiving x-ray examinations of the chest had "significant" disease which was not detected clinically and 0.3 per cent of the total were found to have the active reinfection type of tuberculosis.

Plunkett and Mikol⁴ in 1940 conducted chest x-ray examination of 4,853 patients admitted to general hospitals in upstate New York and found 2.6 per cent with evidence of the reinfection type of tuberculosis. Of these 1.1 per cent had "roentgenological characteristics diagnostic of clinically significant lesions."

Our interest in this demonstration is not confined solely to the yield of new cases of unrecognized tuberculosis but includes the furtherance of our tuberculosis

control program at Grasslands, which has been under way for several years. Our program started in the tuberculosis division in 1932 with routine periodic x-ray examination of employees in that division. Since that time the program has been extended, until now all general hospital employees and students in the nursing school are screened by x-ray chest examinations on entering employment and periodically thereafter. In the nursing school and among young employees in the tuberculosis division, examination is supplemented by tuberculin testing. By discovering unsuspected tuberculosis in our patient groups we can isolate infectious patients and better protect our staff.

Tuberculosis case finding has been intensified during the past few years in various groups of the population. Reports of community surveys, home relief groups, inmates of institutions, schools of various types, industrial workers and apparently healthy groups have appeared in the literature. Perhaps the most noteworthy is the present program of routine chest x-ray examination of inductees into the various branches of the armed forces where, according to Long⁵ "the army examinations constitute the greatest case finding survey the world has ever seen."

Edwards⁶ and his co-workers from 1933 to 1940 examined 388,666 individuals by x-ray in New York City, and the tuberculosis division of the New York State Department of Health has been instrumental in examining large numbers in schools, hospitals and industry and is now in the process of examining thousands of individuals in mental institutions.⁷ According to press reports the Swedish National Association Against Tuberculosis⁸ is planning to take chest x-ray films of all citizens of the country. The work will be done by mobile x-ray units.

Although tuberculosis case finding programs among various sections of the population have increased, the opportunity of the general hospital with its x-ray equipment has not been fully utilized. Parran⁹ in a recent report outlines a tuberculosis control program for the United States Public Health Service and among other steps in the program emphasizes encouragement and assistance in the establishment of chest x-ray examination procedures in the admitting rooms of general hospitals.

Even though greater yields are reported in many other selected groups of the population, by the examination of general hospital admissions tuberculosis can be discovered in unbridled and unisolated individuals and is therefore of greater importance from the standpoint of tuberculosis control. In addition the general hospital often houses the most substantial x-ray equipment in the community and could be used for screening with a minimum of dislocation of material and personnel.

In days of wartime emergencies of all types, limited funds and personnel shortages, one may ponder the advisability of launching such a program. However, the importance of this demonstration looms before us when we consider that based on the figures of approximately 53,000 annual admissions to general hospitals in Westchester County, in terms of our yield approximately 300 active or questionably active cases of tuberculosis would be discovered annually and in about 150 of these open disease would be expected.

We consider it sufficiently important to preserve most of the program at Grasslands and to recommend it as a profitable source of tuberculosis case finding for general hospitals.

CONCLUSIONS

1 The opportunity offered by routine x-ray or fluoroscopic chest examination of adult admissions to general hospitals as a source of tuberculosis case finding has not been fully utilized.

2 A tuberculosis case finding demonstration for unsuspected pulmonary tuberculosis by the aforementioned methods has been carried on at this hospital for a period of eighteen months, dating from July 1, 1941 to Jan. 1, 1943.

3 Approximately 4 per cent of patients who would not otherwise have been detected were shown to have evidence of tuberculous infection. Of these 28 per cent had reinfection disease and 0.6 per cent had active or questionably active disease requiring hospitalization or close observation.

4 This group is particularly important from a public health point of view because of the ease of transmitting the disease to others.

5 By discovering previously unrecognized tuberculosis in the patients, better protection for the hospital worker is made possible through isolation and treatment of infectious cases.

THE PREPARATION AND USE OF RED BLOOD CELL SUSPENSIONS IN TREATMENT OF ANEMIA

LIEUTENANT CLIFFORD K. MURRAY

During the past few years there has been a definite increase in the use of blood transfusion as a therapeutic measure. The improved methods and facilities for collection, preservation and administration of blood, the development of blood banks, a better understanding of the therapeutic value of and indications for blood transfusion, and the increased requirements due to military medicine are probably the factors which are responsible for this increased interest. The present war has also intensified interest in the use of human blood plasma in the treatment of shock, burns and hemorrhage. Experimental and clinical observations have established the fact that plasma is actually more valuable in the treatment of shock and burns than is whole blood. The transfusion of plasma is now and will continue to be, of increasing importance in military medicine.

The large scale preparation of plasma from whole blood has made available great quantities of red blood cells which are usually discarded. We have attempted to utilize these red blood cells which are a by-product of our plasma bank (and which amount to about 46

per cent of the original volume of whole blood) in the treatment of anemia

The most important factor in any type of anemia, no matter what the cause, is a deficiency in functioning erythrocytes, and the rationale of treatment is essentially replacement therapy. Whole blood transfusions are used to supply red blood cells in severe and resistant cases of chronic anemia and to hasten the recovery period in anemia from blood loss. Although the transfusion of suspensions of red blood cells is not an entirely new therapeutic procedure, its use has not been widespread. In 1937 Castellanos¹ in Spain called attention

Scudder at the Presbyterian Hospital in New York has employed infusions of red blood cells and that red blood cells salvaged from the Detroit Red Cross Center have been used to supplement whole blood transfusion⁶

PREPARATION OF THE SUSPENSION

The red blood cells which remain after the plasma has been aspirated by means of a closed aseptic technique are used for the preparation of the red blood cell suspension. After the plasma is removed, the aspirating needle is plunged to the bottom of the red blood cell layer and 200 cc of cells is drawn over by means of

to the advantages of an infusion of concentrated red blood cells. In 1940 MacQuaide and Mollison² in England described the use of erythrocytes in concentrated suspensions for the treatment of anemia, and in the next year Williams and Davie³ presented a series of cases. In 1942 Bagdasarov⁴ in Russia described the use of conserved red blood cells in the treatment of anemia. In this country it has been reported⁵ that

a vacuum into a sterile 300 cc dispensing bottle which contains 100 cc of 5 per cent dextrose in isotonic solution of sodium chloride. The buffy coat or gel which lies between the packed red blood cells and the supernatant plasma and which consists of white blood cells, platelets and fibrin is left behind in the bottle which was used for collecting the blood. The final suspension contains approximately 88 per cent of the red blood cells obtained from one donation of 500 cc of whole blood. The cells are from 24 to 48 hours old when they are aspirated into the dispensing bottle. They are then stored in a refrigerator at 2 to 5 C for a maximum period of seventy-two hours, after which time those not used are discarded. The suspension of

6 Red Blood Cells Salvage, Science News Letter 43 113 (Feb -) 1943

red blood cells is typed and cross matched with the serum and cells of the recipient and is also examined for hemolysis, which, if present, is sufficient reason for discarding the suspension. An analysis of the suspension reveals averaged values as follows: a hemoglobin of 17 Gm per hundred cubic centimeters, a red cell count of 6,180,000 and a white cell count of 2,000 per cubic millimeter.

RESULTS OF TREATMENT

In the past ten weeks more than 116 infusions of red blood cell suspensions were administered to patients with anemia at the Naval Hospital, Philadelphia. No difficulty was experienced in the administration of these red cell suspensions. A filter of the type used in the administration of whole blood was employed and the rate of flow did not exceed 10 cc per minute. The data obtained from a careful study of 72 of these infusions in 48 patients was tabulated. A red blood cell count together with a hemoglobin determination (Haden-Hausser method) was done before the first infusion was administered and two days after the last infusion was completed. Although it is impossible to achieve mathematical precision in the hemoglobin rise per volume of red cell suspension because of the many variables involved, the average increase in hemoglobin was approximately 1 Gm for each 300 cc suspension of red blood cells. A questionnaire was sent to the ward with each bottle of red cell suspension to be filled out by the medical officer in charge, in order to attempt to evaluate the clinical improvement. Beneficial results were reported in all but 4 of the 48 cases. There were two pyrogenic reactions, one slight and one severe in nature. There were no reactions of the hemolytic type.

Two cases of pernicious anemia were treated, one of sufficient severity to deserve special comment.

J. H., a man known to have pernicious anemia, was admitted to the hospital on March 19, 1943, in a moribund condition. The red blood count was 650,000 per cubic millimeter and the hemoglobin 2 Gm. The diagnosis on admission was hyperchromic macrocytic anemia with combined degeneration of the lateral and posterior columns of the spinal cord. He was given five infusions of 300 cc of red blood cell suspension over a period of ten days during which time parenteral liver therapy was withheld. The blood count was elevated to 3,130,000 per cubic millimeter and the hemoglobin to 11 Gm per hundred cubic centimeters. The patient was then placed on liver therapy and was discharged from the hospital on April 29, 1943, with a well defined clinical improvement. In 1935 the patient had been hospitalized at this institution for eleven months with the same condition.

The accompanying table shows the results of the use of 72 infusions of red cells in the treatment of anemia in 48 patients. There is 1 case of anemia secondary to thrombocytopenic purpura and 2 cases caused by acute infections. Whole blood would have been more suitable, but since the available donors were not compatible these patients were given red cell infusions.

SUMMARY AND CONCLUSIONS

1. It has been estimated that 50 per cent of the patients requiring blood transfusions in a large hospital probably need only red blood cells, and, since large quantities of these red blood cells are now being discarded in the preparation of plasma, it is logical that they be utilized as suspensions in the treatment of anemia. In time of war, when hospital beds are not plentiful and convalescence can be hastened by the administration of these red cell infusions, their use is of great value.

2. At the Philadelphia Naval Hospital 116 infusions of red blood cells have been administered in this series with only two reactions, an incidence of 1.72 per cent.

3. The data obtained from a careful study of 72 of these infusions in 48 patients were tabulated. The average rise in hemoglobin for each 300 cc suspension was approximately 1 Gm and all but 4 of the cases showed clinical improvement.

4. The results show that a waste product may be converted into an effective therapeutic agent in the treatment of anemia.

SHOULD AMERICAN MEDICINE BE SOCIALIZED?

WILBURT C. DAVISON, M.D.

DURHAM, N. C.

Perhaps the simplest as well as the most comprehensive definition of socialized medicine is that it is any organized method by which adequate diagnostic and therapeutic medical service can be made available to all of the people, regardless of their ability to pay. This article, which is based on the foregoing definition, is merely an attempt to present as fairly as possible the opposing statements gleaned from the controversial literature.

The main question facing the public and the medical profession is not *Will medicine be socialized?* but *Will socialized medicine be extended?* for in the broadest sense medicine has been partially socialized, though unorganized, since the earliest Christian era.¹

At present in this country medical care is given under a variety of systems: (1) public services, (2) services financed through insurance under the workmen's compensation acts and voluntary schemes, (3) industrial group medical services, (4) charitable and philanthropic services and (5) private competitive medicine. The problem at present is not one of "socialization" but whether the proportion between the various types or existing services shall remain the same or shall be changed.² Four important trends in the distribution of medical care have been under way for some time: (1) the development of group medical practice, (2) the growth of tax supported medical care for needy and other persons, (3) the planned distribution of medical facilities and personnel and (4) the growth of health insurance.³ The two questions that should be answered are: (1) Is the present system adequate for our needs?

From the Department of Pediatrics, Duke University School of Medicine and Duke Hospital.

¹ Hospitals and dispensaries established by the early church and later by private endowments gave unorganized socialized medical care to millions of the poor. Experimentation in new forms of distributing medical services has been taking place for many years throughout the United States. In 1773 Virginia provided institutional care for the insane. In 1800 the federal government built the first Marine Hospital at Norfolk, Va., to give medical service to sailors. From 1800 to 1884 as authorized Nov. 13, 1797 by the Fifth Congress the Marine Hospitals were financed through a tax of 20 cents a month later increased to 40 cents deducted from the wages of each seaman and collected by the Collector of Customs. This plan probably was the first of the voluntary hospital care associations which have become so numerous during the last decade. In 1802 another Marine Hospital was established at Boston and others followed along the Atlantic Seaboard and the Mississippi and Ohio rivers. In 1890 state hospitals for tuberculosis appeared. In 1901 crippled children became patients of the state. In 1910 North Carolina and Virginia commenced the free treatment of hookworm patients. In 1921 the veteran hospitals began to multiply. In 1921 the National Leprosarium was purchased. In 1922 federal narcotic farms were established and in 1935 the federal and state governments provided free diagnosis and treatment to syphilis, pneumonia, cancer and malaria. During the past generation but one of the states have paid workmen's compensation laws. For the last ten years the Children's Bureau of the U. S. Department of Labor has financed state infant and maternal programs and to graduate nurses in obstetrics and pediatrics or general practitioners.

and (2) If not, will "further socialization" improve the situation?

The national health or Wagner and similar bills authorize grants in aid to states to "extend and improve medical care as far as practical under the conditions in such state, especially in rural areas and among individuals suffering from severe economic distress" with "standards of medical and institutional care and of remuneration therefor prescribed by the state agency after consultation with professional advisory committees".⁴ Although these bills do not require the states to adopt compulsory health insurance, it is conceivable that some of them would.

The "model bill" of the American Association for Social Security, which has been used as the basis for some proposed legislation, provides complete medical and hospital service, cash disability and maternity benefits for employes receiving less than \$60 a week and for their dependents.⁵ The cost is to be borne by a 6 per cent tax on pay rolls, three fourths of the money going for medical and hospital care and one fourth for the cash disability and maternity benefits, with the details of operation and payments left to local councils under state supervision.

ARGUMENTS FOR CHANGING METHODS OF DISTRIBUTING MEDICAL CARE

Affirmative—Advances in medicine have increased both cost and benefits and intensified the need of medical care. Inability to pay for medical care leads to vast expenditures for "patent medicines" and the services of cultists. Hospital care given to those who might be served by a prepayment plan is exhausting hospital endorsements. Physicians on the average are still underpaid in comparison with the cost of medical education.

Although health conditions are better here than abroad, one third of the registrants in the first and second world wars were rejected for physical defects, many of which were remediable.

Negative—To this the negative side replies. When fully analyzed, the survey of the Committee on the Costs of Medical Care showed that only 5 per cent of those presumed to be in need of medical care failed to obtain it.⁶

No one in need of medical care has been denied it.⁷ Many surveys show that failure to secure such needed care is due primarily to failure to obtain knowledge of where service was available and refusal or neglect to obtain service and in only about 3 per cent to ability to pay.⁸

Every one who has studied the subject without prejudice admits that American medicine, American medical education and American health are better than those in countries with compulsory socialized medicine. However, it has been suggested that the American standard of living and health departments may be responsible and not the American medical service and that our health record might be even better with an extension

of socialized medicine. The essential difficulty of the present situation is the uneven distribution of the costs of medical care.

VOLUNTARY HEALTH INSURANCE

Voluntary health insurance is urged by many who say "The public should be encouraged to take out hospital and health insurance policies which will provide cash benefits sufficient to pay hospital and medical bills."⁹ These policies are now available through voluntary nonprofit associations and commercial companies. Citizens should also be encouraged to form their own medical cooperatives on the prepayment plan, and industries should be compelled either to establish medical services of their own or to contract for medical service with local groups of physicians.¹⁰

The fear that voluntary health associations will lead to compulsory health insurance is valid only if these associations are badly managed.

The opponents of voluntary plans reply "Health insurance policies may cause some persons to 'enjoy ill health' because of the financial return, they do not provide many preventive measures, minor illnesses may be neglected, and competing groups may render inadequate service in order to cut the rates and force payments to physicians to an unbearable level."

Health insurance groups are restricted to the medical personnel employed, choice of physicians and the individualism of physicians usually are lost. Many of the physicians employed by these groups probably are excellent and possibly better than those whom the members would have selected. Unless they have freedom of choice, many people do not have the confidence in their physicians which, foolish or illogical though it may seem, is a sine qua non of successful medical care.

Except indirectly by larger support to medical institutions, health insurance, either voluntary or compulsory, does not provide medical care directly for the indigent, does not provide for prolonged illness and is distributed over the low income class, which is least able to bear it.⁶ Most of the group plans are not applicable to the rural population.

Voluntary plans may lead to compulsory health insurance.

COMPULSORY SICKNESS INSURANCE

If voluntary insurance is not satisfactory, it is next urged by the advocates of compulsory sickness insurance that medical service should be made a public service, financed through taxation and available to all without charge, like the public schools. Medical services must be organized in order to reach the whole population and to be efficient.¹¹ People with low incomes—those who most need insurance protection—do not know enough to protect themselves and should be compelled to do so.⁷ Without some form of compulsion, voluntary insurance fails of its objective of distributing the cost of sickness among large classes of the population with even approximate fairness. The young and healthy will not join, the acceptance of the aged and sickly will raise the cost to a prohibitive point, but their rejection will remove protection from those most in need. Sickness insurance cannot distribute the burden of sickness among the low income classes unless it is compulsory.¹²

12 Bureau of Medical Economics. A Critical Analysis of Sickness Insurance, Chicago: American Medical Association, 1932.

No country that ever enjoyed the benefits of social insurance has made the slightest move to relinquish them. Health insurance has always brought more money to the doctors. The amount of bureaucracy in compulsory health insurance depends on the physicians: if they are willing to serve on salaries there will be a minimum of red tape, but if they insist on a fee-for-service basis it will be tremendous.¹³

To these arguments it is replied that though there is a decrease in the cost to the average consumer, and medical care becomes more adequate and more accessible to larger numbers, the total cost of medical care is increased owing to the employment of numerous lay organizers and bureaucrats who control medicine and become undemocratic politicians.¹⁴

Morbidity and mortality are not reduced, diagnosis and treatment are mechanical and superficial, neuroses are created, overmedication is increased, the hospital load is increased, hospitals are encouraged to practice medicine, the loss of time from employment through illness is greater, malingering is increased and the quality of medical care is worse. The confidential relation between patient and physician is destroyed, the former's private affairs become a matter of public record.¹⁵

The employment of part or full time physicians has resulted in low salaries, heavy case loads, regimentation, reduced medical standards, little opportunity for advancement and loss of initiative and personal contact.¹⁶ The patients also are dissatisfied under state managed medicine.⁶

Even the best systems furnish an incomplete service without hospitalization, surgery or specialties, have a tendency toward routine and slipshod medical service and omit medical care for dependents, the self employed, shopkeepers, farmers and others.⁷

ATTITUDE OF MEDICAL PROFESSION

The medical profession today is conducting more social experiments in the methods of distributing medical services than all the proponents for change have ever conducted. Out of the two hundred and fifty or more projects that are being studied or operated by county or state medical societies, it is hoped that methods may be found to supplement existing medical facilities wherever necessity demands. These experiments in the distribution of medical care have been encouraged and studied by the American Medical Association and analyses of their advantages and disadvantages have been compiled by the Bureau of Medical Economics.¹⁷ The medical profession has opposed some of the methods of distributing medical service for the reason that experience has shown the impossibility of providing good and sufficient medical care under such arrangements. In other instances the proposals have met with medical approval as presenting the most satisfactory method thus far found to provide good medical care for the conditions or communities concerned.⁸

The platform of the American Medical Association advocates the federal supplement of state funds for the care of the sick, the amplification of medical care for the indigent, the utilization of established medical and hospital facilities in the extension of medical service to all the people with local determination of needs, local responsibility and local control of administration and the coordination of all medical and health functions of the federal government in a National Department of Health with a physician as a member of the cabinet.¹⁸

The American Medical Association is not opposing the low income groups in this country in their effort to secure good medical service at a cost which they can reasonably meet. It has endeavored to discover more suitable methods to assist these people to solve their medical problems. It does oppose the exploitation of the poor, and it is unalterably opposed to any scheme that would give the poor an inferior quality of medical care.⁹

Both sides believe in medical care for all the people, but the "pros" believe that the present situation is intolerable and want an immediate change by legislation, while the "antis" believe that the present method of distribution of medical care can be gradually improved by local experiments and that it is impossible to apply a single universal plan to all parts of the country for the entire population or even for the forty million underprivileged people.⁸

To proceed rashly without going through progressive stages will produce worse medical service than exists under the present system. Ill considered and hasty legislation is as likely to be harmful as beneficial. Whether a generation will be necessary for the transition or a century, as in public education, only sound experiment and experience can tell.

Any organized method by which adequate diagnostic and therapeutic medical service can be made available to all of the people regardless of their ability to pay, should meet the following requirements:

1 The public should be educated to seek early medical care.¹⁹ The socialization of American medicine is being and will continue to be extended. However, if the expansion proceeds too rapidly without educating the public to the need for adequate medical care and without obtaining the cooperation of the medical profession, the resulting medical service will be worse than it is now.

2 Physicians, and good physicians, are essential to any plan of medical care, and if it is to be adequate it needs the wholehearted support of the medical profession. Medical service of sorts can be obtained by regimenting physicians against their better judgment, but the cooperation of the medical profession will not be obtained unless experiments demonstrate that the contemplated change in the distribution of medical care is an improvement on the present arrangement.

3 Medical care must be provided for the indigent and his dependents. At present it is available in most areas but is sometimes difficult to find, its quality is often poor and the payment for it usually is absent. Every one agrees that the poorest third of the population needs the most medical care and gets the least. The county medical societies, health departments and public welfare agencies are increasing their efforts to solve this problem. The following methods for pro-

viding medical care to the indigent from local, state or federal funds should be considered. (a) The employment of county and city physicians is the cheapest method for the taxpayer, but the medical service often is mediocre. However, it may be the only practical solution in sparsely settled areas. The payment of larger salaries and the possibility of advancement would attract better physicians. (b) Medical service to the indigent on a fee-per-call basis under the control of the county medical societies, similar to the former FERA plan²⁰ or the present Farm Security Administration program,²¹ has proved satisfactory to the patient and the physician, though it is more costly than the employment of a county physician. (c) Payment to group clinics and hospitals and traveling expenses for the 15 per cent of indigent patients who need specialist, diagnostic, surgical and hospital care are essential. Many counties and states are recognizing this responsibility. (d) Group clinics and hospitals should be provided and supported in areas which need them. (e) Medical care should be separated from unemployment insurance and cash sick benefits.

4 The cost must be distributed for that large section of the population who want to pay their way if they can and who are not applicants for charity but whose budget rarely includes an item for hospital or doctor and to whom severe illness is a serious emergency, often a financial tragedy.⁷ Voluntary associations that provide medical, surgical and hospital care under the control of state and county medical societies are enabling a rapidly increasing number of low income persons and their dependents to obtain adequate medical care without charity or bankruptcy. As the education of the public to the need for good medical care grows, the membership in these groups will increase.

5 Medical care should be improved for every one. If free from political interference and regimentation, the medical profession will be able to continue to improve medical service. Without any compulsion from political or governmental sources, the medical profession has sought constantly to advance the standards of medical education, medical licensure, hospital and specialty practice. To a remarkable degree these objectives are being accomplished. Today curative and preventive medicine has advanced to new and higher planes of efficiency. The medical profession is constantly perfecting methods of diagnosis and treatment, there has been a striking reduction in the prevalence of certain communicable and infectious diseases, infant mortality has been greatly reduced, and in the past century life expectancy at birth has been increased from about 35 years to almost 62 years.⁸

6 Free choice of a physician should be provided, not to protect him as has been charged but because the best results in medical care are obtained when the patient has confidence in his physician.

7 General practitioner care is the greatest need, as 85 per cent of illness can be handled successfully by family physicians. Only 15 per cent of the patients need specialist diagnostic, surgical and hospital care. Economic factors and the specialty boards may decrease the present plethora of specialists.

8 The control and administration should be local in order that specific needs can be met. A plan applicable to a city with several physicians per square mile is not practical in areas with one physician per 200 square miles.²²

9 State or federal loan funds should be available to enable rural students to study medicine. Eighty per cent of them will return to the country, where they are badly needed.²³

10 A coordinated National Department of Health should be established with a physician as a member of the cabinet.¹⁸

11 An equitable system of taxes is necessary to support any extension of the socialization of American medicine.

Clinical Notes, Suggestions and New Instruments

A RENAL CONCENTRATION TEST EMPLOYING POSTERIOR PITUITARY INJECTION

MODIFIED PROCEDURE

WILLIAM A. SODEMAN, M.D., AND HUGO T. ENGELHARDT, M.D.
Professor of Preventive Medicine and Instructor in Medicine, Respectively, Tulane University of Louisiana School of Medicine
NEW ORLEANS

We have previously reported a renal concentration test employing posterior pituitary injection.¹ This procedure consists in the subcutaneous injection into an unprepared patient of 10 units of posterior pituitary injection (1 cc obstetric or 0.5 cc surgical). Specimens of urine are collected at half hourly intervals for two hours and their specific gravities determined.

The small volumes of urine resulting from this procedure require a Savé urinometer, or weighing bottle, for the estimation of the specific gravity. Such a procedure does not lend itself well to clinical practice. We have therefore modified the technic by lengthening the intervals between collections to one hour. This modification is just as satisfactory and requires only the usual small size urinometer. Cheap accurate urinometers requiring only 4 to 6 cc of urine are available. The procedure is as follows:

1 The unprepared subject empties the bladder, and the specimen is saved.

2 Immediately 10 units (1 cc of obstetric or 0.5 cc of surgical) of posterior pituitary injection is given subcutaneously.

3 The subject receives nothing by mouth until the test has been completed.

4 Specimens are obtained at the end of the first and second hours.

5 The specific gravities of the three specimens are then taken, and the usual corrections for albumin and temperature are made, if necessary.

Table 1 shows the results of this procedure on 45 normal medical students. The test was carried out in the afternoon following the usual lunch. No restrictions on fluids or food were imposed on the subjects. The lowest maximum concentration during the test period is seen to be 1.023. This compares favorably with the results of the half hourly test¹ and reaches

the lower limit of normal described for the Fishberg procedure.³

Results of the test in patients with various degrees of renal impairment and with conditions, such as essential hypertension, which lead to renal damage are shown in table 2. Here figures for patients with both compensated and decompensated kidneys are included.

COMMENT

The usual tests for urinary concentration employ periods of water restriction varying from twelve hours to three days. In this way water diuresis is inhibited and the urinary specific gravity is elevated. Posterior pituitary injection eliminates the need for these long periods of water deprivation. The antidiuretic action of these solutions apparently increases the reabsorption of water by the tubules and in this way diminishes the urinary volume. This action takes place even when large amounts of water are ingested. Since the urinary solids continue to be excreted, the specific gravity is elevated to a degree dependent on the dose or effectiveness of posterior pituitary injection, the degree of water diuresis present tubular function and the electrolyte-nonelectrolyte pattern in the urine. We have found that 10 units of posterior pituitary injection

41	1.017	1.019	1.013
42	1.010	1.025	1.019
43	1.012	1.014	1.017
44	1.015	1.023	1.023
45	1.015	1.015	1.024

has been satisfactory, even when amounts of water up to 1,600 cc have been ingested immediately before its administration.² Increasing the dose has not increased the efficiency of the test in our hands. The effect of the electrolyte and nonelectrolyte pattern in the urine and the results of salt diuresis may vary the concentration of substances making up the specific gravity of the urine. We have not evaluated these effects.

Since the highest specific gravities found following the administration of posterior pituitary injection occur in a period varying from one to two hours, the collection of two hourly specimens has been found to be adequate. This procedure not only simplifies the test but gives specimens of adequate volume for the small type of urinometer.

TABLE 2—Results of Test in Subjects with Diseases Producing Renal Damage

Subject	Diagnosis	Specimen Before Posterior Pituitary Injection	Specimen 1 Hour After Posterior Pituitary Injection	Specimen 2 Hours After Posterior Pituitary Injection

18	Essential hypertension	1.021	1.021	1.020
19	Uremia malignant hypertension	1.005	1.011	1.009
20	Malignant hypertension	1.010	1.020	1.024

The concentration tests now in use give various values for the specific gravity of urine in normal subjects. Prolonged periods of water restriction may give higher values than are obtained with posterior pituitary injection. However, we have in the same subjects obtained better results with posterior pituitary injection than with water restriction up to sixteen to eighteen hours. Obviously the procedure like other tests for renal concentration does not give a ceiling specific gravity, but the standards set up for normal subjects are workable ones. Pasqualini and Etala⁴ in a series of 18 subjects in whom the specific gravity started in a low range found in the face of the ingestion of 1,000 cc of water elevation of the specific gravity to 1.025 or more. These results are similar to ours. Others⁵ also have found the procedure a satisfactory one.

Since impairment of renal tubular function may be estimated by determination of an impaired concentrating ability of the kidney, the test is useful in patients with disturbances in renal tubular function. In such patients posterior pituitary injection as well as deprivation of water will indicate the degree of tubular damage. Under these circumstances there is a striking parallelism in the results of the tests employing water restriction and the results of that employing posterior pituitary injection.²

In both normal and abnormal groups the doses of posterior pituitary injection used have not produced significant changes in the blood pressure even in the presence of severe hypertension and uremia. We have not used the procedure in cases of severe oliguria, pregnancy, angina pectoris or myocardial infarction. Posterior pituitary injection administered to patients with angina pectoris has been known to precipitate attacks. However, in arterio sclerotic heart disease with congestive heart failure we have used posterior pituitary injection without the observation of any untoward symptoms. Graybiel and Glerdy⁶ have not found any significant cardiovascular symptoms in

patients with arteriosclerotic heart disease with angina, after slow intravenous infusion of a dilute solution of pitressin in doses adequate to produce pallor and uncomfortable abdominal cramps. Additional contraindications to the use of posterior pituitary injection include epilepsy, in which attacks may be precipitated, and hypersensitivity, which has been reported on several occasions.⁷

There are instances in which the method may be valuable when the usual concentration tests are unsatisfactory. These include congestive heart failure when water diuresis from edema fluid precludes the use of any water restriction technique. Under these circumstances we have used posterior pituitary injection, which sufficiently restricts water diuresis to give an adequate estimate of tubular function. Since the pharmacodynamic effects of posterior pituitary injection last only three to six hours, diuresis is then resumed.

In clinical practice the test has definite advantages. It may be carried out on unprepared patients at any time of day. This is particularly advantageous in office practice in which a patient coming some distance for treatment may be seen only once. Furthermore it is of value in surgical patients in whom restriction of fluids over the period of time necessary for a test by water deprivation may be inadvisable. It is particularly advantageous in edematous patients and under circumstances in which the cooperation of the patient in fluid restriction cannot be relied on.

SUMMARY

The renal concentration test employing posterior pituitary injection has been modified to adapt the procedure to clinical practice. Its satisfactory use in many normal and abnormal persons affirms its efficacy.

ACUTE GOITER DURING THIOCYANATE THERAPY FOR HYPERTENSION

MARGARET P. H. FOULGER, M.D., AND EDWARD ROSE, M.D.
PHILADELPHIA

The sodium and potassium salts of thiocyanic acid have been used intermittently in the treatment of hypertension since Pauli in 1903 discovered their property of lowering blood pressure. Their use, however, was rather restricted until Westphal in 1925 revived interest in the subject. Since that time many reports have appeared relating to their efficacy in the treatment of hypertension¹ and describing various side effects. One of the most remarkable of these collateral effects is the occasional acute enlargement of the thyroid which occurs in patients receiving thiocyanates. Although this phenomenon is mentioned in the course of several papers dealing with thiocyanate therapy,² there have been but few actual reports of such enlargement of the thyroid. We describe briefly such a case to emphasize further the possibility of this type of complication occurring during the administration of thiocyanates for hypertension.

REPORT OF CASE

An Italian woman aged 35, admitted to the hospital on March 8, 1938, complained chiefly of headache and dizziness. Hypertension had first been discovered during her fifth pregnancy, in 1932, but had not received any specific treatment. On examination the blood pressure averaged about 210/110 mm of mercury. There was moderate sclerosis of the retinal arteries with some angiospasm. The second aortic sound was accentuated. The thyroid isthmus was barely palpable. Intravenous urography showed a normally functioning urinary tract with moderate ptosis of both kidneys. Repeated urinalyses were normal. The blood urea nitrogen was 8 mg per hundred cubic centimeters. The urinary excretion of intravenously injected inophthalein was normal. The diagnostic impression was of "benign" essential hypertension.

The oral administration of potassium thiocyanate was begun in doses of 0.3 Gm daily on March 21, and the patient was discharged from the hospital on March 28, 1938. Thiocyanate therapy was continued in doses sufficient to maintain a blood concentration of 6 to 10.5 mg per hundred cubic centimeters until July 1939. During this period, however, there was little subjective or objective improvement. In June 1938 the patient was referred to the Endocrine Section of the Medical Clinic because of suspected hyperthyroidism. Although the basal metabolic rate at that time was +36 per cent and fell to +20 per cent after nine days of iodine therapy, the patient felt no better as a result of taking the iodine. It was concluded that there was no valid evidence of hyperthyroidism, the increased basal metabolic rate was thought to be associated with her hypertension, as is often the case. However, because the thyroid isthmus was palpable a semiannual period of prophylactic iodine administration was advised. On Oct 24, 1938 the basal metabolic rate was +9 per cent and on Oct 21, 1939 it was +5 per cent. In July 1939 her blood pressure was 175/110 and the blood cyanate concentration was 10.5 mg per hundred cubic centimeters. There was no apparent change in her condition until August 1940. At that time she noted a sense of chilliness, sluggishness, impairment of hearing, pain in the neck and swelling of the face and throat. In September 1940 she returned to the Endocrine Section for examination. At this time she exhibited general sluggishness, with puffiness of the face and a definite soft diffuse uniform enlargement of the thyroid. The thyroid gland was not tender, but lateral motion of the head caused pain in the neck. The heart rate was 76, the blood pressure 195/120, the basal metabolic rate -11 per cent and the blood cholesterol 223 mg per hundred cubic centimeters. The blood cyanate concentration at this time ranged from 8 to 10 mg per hundred cubic centimeters. The patient was given 0.015 Gm of desiccated thyroid and 0.3 cc of saturated solution of potassium iodide daily from Sept 1 to Nov 25, 1940. Because the relationship between the thiocyanate therapy and the goiter was not appreciated at the time, the administration of thiocyanate was not stopped. On November 25 the basal metabolic rate was -4 per cent and the thyroid enlargement had almost entirely disappeared, as had also the superimposed symptoms which had appeared in August. The desiccated thyroid and potassium iodide were stopped at this time, but the thiocyanate was continued under the direction of the Cardiovascular Section.

The patient returned to the Endocrine Section every six months for inspection and a ten day period of prophylactic iodide medication. There was no change in her symptoms or thyroid status until August 1942. At this time there was a recurrence of the symptoms noted two years before, i.e. puffiness of the face and neck, sluggishness, chilliness, impairment of hearing and pain in the region of the thyroid on motion of the neck. These symptoms, however, were less severe than at the time of their first appearance in 1940. Examination again showed puffiness of the face and a diffuse soft uniform swelling of the thyroid gland, which on this occasion was quite tender and slightly firmer than during the first episode. The temperature was 99.4 F and the blood pressure was 200/110. The basal metabolic rate was -18 per cent and the blood cholesterol was 172 mg per hundred cubic centimeters. The blood cyanate concentration was less than 4 mg per hundred cubic centimeters, despite the long duration of uninterrupted thiocyanate therapy and the fact that the patient was taking 0.65 Gm of potassium thiocyanate daily at the time. A blood count and routine urinalysis showed no abnormality. The thiocyanate was stopped and the patient was again given 0.015 Gm of desiccated thyroid and 0.3 cc of a saturated solution of potassium iodide daily. This medication was continued from Aug 6 to Oct 16, 1942. On Sept 17, 1942 the basal metabolic rate had risen to +13 per cent, the thyroid enlargement was subsiding and the patient's symptoms were improving steadily. On Dec 9, 1942 the basal metabolic rate was +9 per cent, the blood cholesterol was 172 mg per hundred cubic centimeters and the puffiness of the face and the enlargement of the thyroid had entirely disappeared. On that date the patient said that she felt better than she had for a number of

of years, despite the failure of prolonged thiocyanate therapy to produce a sustained significant fall in her blood pressure. The administration of thiocyanate was not resumed after the last episode of acute enlargement of the thyroid.

COMMENT

While there has been some speculation concerning the manner in which acute goiter is related to thiocyanate therapy, there have been but few specific cases reported in the literature. Barker¹ in 1936 referred to 3 cases that showed a peculiar myxedematous swelling of the tissue of the face, the orbital areas and the cervical region while thiocyanate was being taken. One occurred in a woman after one year and the other occurred in a woman after fifteen months of administration of thiocyanate. In the latter case a large thyroid, swollen face and heavy jaw developed. The basal metabolic rates were only slightly reduced (—18 per cent and —19 per cent). In 1 man a diffusely enlarged thyroid developed after ten months' administration of thiocyanate. His basal metabolic rate had fallen from +19 to —9 per cent. The enlarged thyroid returned to normal size on administration of desiccated thyroid. Wald, Lindberg and Barker² in 1939 referred to a patient who showed rapid enlargement of a previously present "adenomatous" thyroid nodule which occurred during thiocyanate administration. In reporting the results of thiocyanate therapy in a series of 246 cases in 1941 they³ mention the occurrence of enlargement of the thyroid in 11 cases and of myxedematous facies in 9 cases. They stated that the thyroid phenomenon disappeared within two weeks in all cases after the administration of small daily doses of desiccated thyroid was begun. Fahlund⁴ in 1942 described an acute tender, painful goiter (probably thyroiditis) in a woman aged 71 suffering from a ten year postoperative recurrence of hyperthyroidism, with associated essential hypertension. The goiter appeared nine days after daily administration of a 6 grain (0.4 Gm) dose of thiocyanate was begun and was accompanied by dermatitis medicamentosa and gastrointestinal disturbance. The signs and symptoms subsided after the withdrawal of thiocyanate and the administration of phenobarbital and potassium iodide. Kobacker⁵ in 1942 described a case in which full-blown myxedema appeared during thiocyanate administration, disappeared after withdrawal of the drug and reappeared when therapy was resumed a year later. Means⁶ has recently referred to a curious case to be reported by Rawson, Hertz and himself. Their patient was a man under prolonged thiocyanate therapy for hypertension who suddenly developed a rapidly growing goiter with bruit, exophthalmos, hypothyroidism and low level of iodine in the blood. Biopsy showed "wildly growing and impotent thyroid cells." The thyroid reverted to normal and the hypothyroidism disappeared after withdrawal of the thiocyanate.

A satisfactory explanation has not yet been found for the occurrence of changes in the thyroid during the administration of thiocyanates. Enlargement of the thyroid in rabbits and guinea pigs following the ingestion of winter cabbage and Brussels sprouts was described in 1928 by Chesney, Clawson and Webster⁷ and later by Marine and others⁸. It was eventually shown that the goitrogenous agent in these foods was methyl cyanide. This was believed to cause sufficient anoxia of tissue cells to result in a work hypertrophy and hyperplasia of the thyroid in an effort to produce increased amounts of thyroid hormone as required by the need to maintain oxidative processes at normal levels. These observations naturally suggest that thiocyanates may produce goiter in a similar manner. Against this theory however, seems to stand first the fact that the cyanate ion (SCN) remains intact in the body without

loss of the sulfur component and, second, failure of the cyanate ion to leave the intercellular tissue spaces and enter the cells themselves.⁹ It is of interest that some of the toxic effects of thiocyanates as reflected in the skin and mucous membranes closely resemble those of iodides.⁹ We have observed that in some hypertensive patients showing a favorable response to thiocyanates there seems to be a somewhat sedative effect with slowing of the heart rate, relief of nervous tension and sometimes coincidental loss of hair. Whenever change in thyroid function occurs during thiocyanate administration it seems to be in the direction of hypothyroidism. Most of the reported cases of goiter have developed after rather protracted periods of therapy, but the actual dosage of the drug and its concentration in the serum do not seem to bear a constant relationship to the thyroid disturbance. The prognosis for disappearance of the goiter and the hypothyroid phenomena seems to be good following the withdrawal of thiocyanates. The administration of desiccated thyroid and iodides probably facilitates recovery. It is of some interest that our patient's first attack of enlargement of the thyroid and the associated phenomena subsided after the administration of desiccated thyroid substance and iodides, despite the continued administration of thiocyanate.

TOXIC ERUPTION DUE TO AMPHETAMINE SULFATE
AND ITS ANALOGUE DEXTROAMPHETAMINE
SULFATE

S. S. KAUVAR, M.D., E. J. HEUSCHEL, M.D., AND
ABE RAVIN, M.D., DENVER

In the last decade more than half a hundred articles on the therapeutic value of amphetamine sulfate (benzedrine) have appeared in the medical literature. Within the last few months its analogue dextroamphetamine sulfate (dexedrine), which qualitatively is similar, has been introduced to the medical profession. It presumably has all the advantages of amphetamine sulfate but causes fewer undesirable vascular reactions.¹

In spite of its increasing widespread use in medical practice, and although numerous toxic reactions have been reported,² a thorough review of the literature of the last ten years reveals but 1 questionable instance of dermatitis.³

The well known untoward cutaneous reactions of amphetamine sulfate have been reviewed by Reifenstein and Davidoff,² who list flushing of the face, urticaria, cutis asperna, characteristic bromidrosis, dermatographia, pustular eruption, cyanosis, xeroderma, coldness and clamminess of the hands, paresthesia and similar effects.

Goldsmith³ presented a questionable eruption on the face of a female patient. There were a number of irregularly disposed flesh colored papules on the forehead and cheeks, some of which were excoriated. The main sensation was prickling, the rest of the skin was normal. The eruption appeared following the administration of amphetamine sulfate for narcolepsy. The rash was exacerbated by increasing doses of amphetamine sulfate and improved when it was withdrawn. Goldsmith had never seen an amphetamine rash. The original diagnosis was acne excoriee, but the paucity of scratched papules and discoloration made him consider a toxic process.

REPORT OF CASE

A S., a white woman aged 34 consulted one of us for obesity and was put on a regimen of 1200 calories and 1 grain (0.065 Gm) of thyroid daily. After several weeks amphetamine sulfate 5 mg before breakfast and lunch was added to the program. The patient then lost approximately 2 pounds (900 Gm) a week for six weeks. In a few days subsequent to the ingestion of amphetamine sulfate a pruritic lichenified eruption developed on the sides of the neck, axilla, cubital fossae and

popliteal fossae. The lesions were the exact counterpart of a typical atopic dermatitis.

She was taken off amphetamine sulfate medication and in a few weeks her dermatitis cleared up entirely. Although she continued on her restricted diet and thyroid medication, she observed that she was no longer losing weight and on her own initiative resumed the amphetamine sulfate. Her rash promptly recurred and she again lost weight. When the amphetamine was again eliminated, the rash subsided except for a mild nonpruritic lichenification of the cubital fossae. She then went on a trip and discontinued her reducing regimen. When she returned several weeks later she had regained half the weight lost and she resumed her previous diet and medication. Once more her atopic dermatitis-like lesions reappeared and the amphetamine sulfate was stopped. Some six weeks later, when the cutaneous manifestations had almost vanished, the patient was put on 5 mg of dextroamphetamine sulfate (dextedrine) before breakfast and lunch, and the dermatitis manifested itself, as seen in the illustration, but disappeared shortly

after the withdrawal of the dextroamphetamine sulfate.

COMMENT

Dermatitis medicamentosa has been reported as resulting from almost every type of medication. Hence it is inevitable that a case of amphetamine sulfate dermatitis should be encountered. It is not uncommon for dermatitis medicamentosa to mimic classic dermatologic entities, thus a lichen planus-like rash may follow the administration of arsphenamine.⁴ An erythema nodosum-like eruption may be produced by sulfathiazole.⁵ Our patient had no personal or family history of allergy. Although emotional factors may precipitate latent atopic dermatitis in a subject with an allergic diathesis,⁶ we do not think the sympathicomimetic stimulation of amphetamine sulfate has

Dermatitis of cubital fossa following administration of dextroamphetamine sulfate.

evoked a dormant atopic dermatitis in this case. Patch tests and scratch tests with amphetamine sulfate elicited no reaction. Goldsmith's questionable case of amphetamine eruption³ may have been acne vulgaris, as he thought was possible. The patient may have excoriated her acne papules in response to the stimulant action of the amphetamine sulfate on her nervous system.

SUMMARY

An atopic dermatitis eruption resulted from the ingestion of amphetamine sulfate and its analogue dextroamphetamine sulfate.

THE ARMY MEDICAL LIBRARY

ITS HISTORY AND ITS FUTURE OBLIGATIONS

COLONEL HAROLD W. JONES

MEDICAL CORPS, UNITED STATES ARMY

Librarian, Army Medical Library

THE FIRST HUNDRED YEARS

Seven years ago the Army Medical Library celebrated its one hundredth anniversary in the building into which it moved in 1887 and which it still occupies. It had been in existence ever since the Florida war, it was a feeble infant in the Mexican struggle, a mere child in the Civil War and lived at all only because John Shaw Billings put the breath of life into it about 1868, when it boasted no doubt of its five thousand volumes. It became great in the succeeding decades, but it has had its ups and downs ever since. It produced, besides Billings, Garrison and Fletcher, neither of the latter two ever to be the librarian, and it has had some fourteen military librarians who held office from a week to nine years, the longest tenure since Billings' time. Most of the librarians, I suppose, have left some impress on the institution. All have been military officers and some were brilliant men, if untrained in library technique.

In my first few years as librarian I was asked occasionally what its policy was, what the organization was, what was the great objective and so on. Apparently, as an institution the library had no definite policy beyond habit and custom, except as is contained in Public Resolution No. 8 of the Senate and House of Representatives (approved April 12, 1892). This permitted the library to place its facilities for research at the disposal of scientific investigators and qualified students of higher institutions of learning. Nevertheless, its organization was somewhat of a mystery, even its employees were mysterious. Certain people had duties and, no less, rights. If an old employee had been holding down an office like, let us say, the steward of the British Chiltern Hundreds at a nominal salary, he was not likely to tell you much about his job. Certainly the library did not always know where its next thousand dollars was coming from and it had no precisely formulated policies. Its obligations, as laid down in Army Regulations, were somewhat nebulous. Even today they are still only what the librarian and the Surgeon General safely think they should be. Do not be surprised at this. The military service can operate only from a day to day basis. At any moment military policies may demand changes affecting the entire army, and retrenchments may produce of necessity far reaching consequences. In this respect the institution has gone through any number of economy storms. It has survived an abortive attempt to take it away from the Army and place it under the Library of Congress. It has suffered disappointments and frustrations without number. For all this it has gone on its way. The Army or, rather, the Surgeon General, has carried on the operations of the Library for many decades and you may be sure that the Army itself can continue to do this to the advantage of medicine and that the Library can retain and augment its rank as a leader in the medical library field in the broadest implication. But it can do this only if it can prove its adaptability.

Read before the Medical Department of the University of Illinois College of Medicine Chicago, May 5, 1943.

to the needs of a changing world and only if it shall arrive at a clear perception of future obligations. Therefore I hope to interest you, not particularly or solely in its wartime work, but in a brief review of the history of the institution, with a consideration of its wartime activities and with its future as we may be able to see it.

Now the Army Medical Library, or the Surgeon General's Library as it was once called, was founded during the administration of Andrew Jackson in 1836. It was then a small collection of medical books and pamphlets, a mere handful in the Office of the Surgeon General, Dr Lovell, and so it remained for more than thirty years, unhonored and unsung. In 1865 John Shaw Billings came to Washington. Dr Billings came not as librarian but as the assistant to the Surgeon General, and at first he appeared more interested in pathologic specimens and in microscopes and fungi than in the library. I have examined hundreds of letters addressed to him in Washington in the years 1868 and 1869, and in none of them could I find any reference to a library and only occasionally was a book mentioned. One of his associates used to call Billings "my dear old fungous fellow," and at that period he apparently did not look on Billings as exclusively a bibliophile. The books numbered but five thousand just before 1870, there was no *Index-Catalogue*, and the present Library and Museum, once the dream of the medical library world, was not occupied until seventeen years later.

In the Surgeon General's report the museum began to be mentioned in 1867, but the library received no mention whatever until 1870, when a brief notice of its expenditures was made. It was not until 1876 that the report contained a headed paragraph on the library, and here is described briefly the printing of the *Specimen Fasciculus*, a momentous event for medicine. From that time on the library's statistics began to appear, and the Surgeon General reported in 1879 that there were fifty thousand books on the shelves. In 1880 the Surgeon General recommended that a new building be constructed to cost \$250,000. The building was completed in 1887.

If we exercise our imagination, it is not difficult to sketch the library of those days in the solemn eighties and the gay nineties except that we must exclude merriment from its somber walls. The Library and Museum shared the building, and the lower floor housed a section of the Adjutant General's Office. There were thousands of books, the *Index-Catalogue*, that monument to Billings' genius and industry was appearing regularly, and other thousands of books and pamphlets were added each year. Appropriations for material were limited and difficulties in obtaining personnel were great. Most of its employees were ex-soldier clerks, a very few of whom were of scholarly pretensions. Garrison, Fletcher, Allemann and Neuman were all of this era, and Toepper came in soon after Billings departed in 1895. The library was useful to a host of scholars, men like Osler, Klebs, Kober, Kelly, Welch and Cushing visited it constantly. Gradually there grew up somewhat of an isolationist attitude which obstinately and forever took refuge in what the library possessed and in its superb *Index-Catalogue* but exhibited no overwhelming desire to know how those outside its walls did or felt. It could not be otherwise when clerks and workers in subprofessional grades gloried in their ability to do today as was done yesterday and when the building of the *Catalogue* must subordinate every other activity. Yet this is not to deny that it held a vast pride in its well earned reputation.

Dr Billings did two notable things among his many accomplishments. He made a vision of a great index catalogue of medicine come true more than sixty years ago and he accumulated a store of medical literary treasures of the fifteenth, sixteenth, seventeenth and eighteenth centuries such as can hardly be equaled again. His ability to secure this material, now unobtainable, was beyond compare.

Billings left the library after thirty years as librarian in the closing years of the last century. The value of his services has been elaborated by abler pens than mine and I forbear to say more, for there is little that can be added. The staff was getting on in years, some were aging and most were set in their ways, to differ with them was heresy.

When Colonel Billings departed with his laurels to take his new position as the head of the public libraries of New York City, he was succeeded by Colonel Huntington, who served but a year, to be followed by Major J. C. Merrill, a distinguished naturalist and bird lover, who carried on for four years. In 1902 there came Major Walter Reed, who seems to have served actually but a week, having died in office. I can find no records which indicate that Major Reed exercised any influence on the Library itself. After Reed's melancholy and untimely death came Brig. Gen. Calvin DeWitt, who served only a year. Thus after Billings' departure in a period of eight years we find that there were five librarians, one of these serving four years and the others averaging only one year. Fortunately the staff was comfortably, not to say firmly, settled and there were always Garrison and Fletcher, brilliant men both. Garrison, so famed in the history of medicine, carried on the *Index-Catalogue* and Fletcher edited the *Index Medicus* and was justly regarded as the father of the latter publication.

The *Index Medicus*, now published by the American Medical Association here in Chicago, was begun in 1879 and except for a brief interval was carried on until 1927. In 1912 Fletcher, who had been regarded as immortal, died of old age, and Garrison became the editor. In 1903 General McCaw became librarian, remaining in this position more than nine years, until a newly adopted War Department policy which limited a tour of duty to four years forced him to leave the city of Washington. He was succeeded by Col. C. C. McCulloch who served for five years, until the end of the World War in 1919, when the Library had two librarians in less than one year. Up to 1919 the librarians had been limited to four years or occasionally a little more, and this applied to the succeeding tours of General Noble, Colonel Phalen, Colonel Ashburn and Major Hume. As each librarian went his way there was a period of uncertainty, and the incoming librarian had to decide what new policies he would adopt or whether he would carry on like his predecessors.

In 1933, to the surprise and consternation of the Surgeon General, a proposal was actually laid before the President by petition of certain members of Congress to transfer the Army Medical Library to the Library of Congress. Fortunately the Surgeon General, aided by the opinions of many of the leaders of the medical profession, was able to prevent this, and not much weight was given to the suggestion as the Librarian or Congress. Dr Putnam opposed it. Nevertheless Dr Putnam seemed to think that the Army Medical Library had not received adequate financial support and that it was not properly staffed, and in this we can agree with him.

During the depression years following 1932 Congress in great measure withdrew its support to the library. The *Index-Catalogue* had to be suspended for three years. To add to this there was not enough money to buy all the necessary journals and many of them lapsed. During this period the librarian, Major Hume, was able to keep some of the journals going by getting the subscriptions as gifts, but this turned out to be unsatisfactory in the following years because later many of the numbers were not sent, which caused gaps to occur in the files. Some of these are still unfilled. Sometimes subscriptions were cut off without notice, which made for confusion.

In 1936 the *Index-Catalogue* was restored to life and began to be printed, but much damage had been done by the lapse of three years and many mistakes were made. Dr. Claudius F. Mayes had been chosen editor some time before and has continued in the position ever since. A change in editorship of the *Index-Catalogue* is usually a serious matter and a new editor requires a number of years before he can carry on successfully. Actually, while there have been many librarians there have been only four editors since Billings' time: Fletcher, Garrison, Allemann and Mayes.

It will be seen that the low point of the library occurred in the period of national depression between the years 1930 and 1936, and those years were disastrous. Material was lacking and personnel so insufficient that much of the indexing, analysis and cataloguing had to be left undone, and this state of affairs continued for many years, which left eventually a vast amount of work which had to be caught up with.

Some years before my time in the library it was realized that the institution was bound to be in difficulties within a few years for lack of space and lack of personnel. In 1938 a bill was introduced after many hearings to provide a new library and museum. After lively agitation and much favorable testimony the bill failed finally in the last few days of the Seventy-Fifth Congress. Long before this a plan for the Army Medical Library and Museum had been formulated at the Army Medical Center. Plans had been made for a building which fitted the needs of the library as a national institution. I entered on my duties as librarian in 1936 and could revise these plans. This I was able to do with good effect, since I believe that the plan was faulty. I was convinced that the location was satisfactory. It is believed I was supported by the leaders of the time and by Dr. Putnam. I thought that it would be of future support to the institution to be placed on the military reservation from the center.

The permanent home of the library on Hill was favored by the Army, General Reynolds as settled when Congress passed and museum. It had a sum of \$130,000 for purchase and artist's drawings were by Eggers & Higgins of New York. It took nearly a year in developing the institution with the librarian and an advisory board of medical officers of Columbia Park Planning Commission. Delano was president, and the

held a number of hearings at which the plans were submitted, and a defense of the ground selected was made by the Surgeon General and myself. The entire plan was finally approved and a square of ground on Capitol Hill was selected for condemnation. Early in the fall of 1940 hearings were begun by the military committee of the House of Representatives concerning the necessary appropriation, since thus far only the enabling act had passed Congress and had been approved by the President. There seemed to be little doubt that Congress would appropriate a substantial sum for the purchase of the land and for the construction of the library, the entire amount of money recommended being about \$4,500,000, of which approximately \$3,750,000 was for the building. Estimates by various construction firms called for an outlay of between \$3,900,000 and \$4,200,000 for the building alone, leaving approximately about a half million dollars for the land, the assessed value of which was about \$450,000.

On Dec 7, 1941 came the war with Japan, and with it were dashed all hopes of the immediate erection of a building which was so badly needed. This was a crushing blow, for the library was already so crowded that there was no hope of holding out any longer. The situation then was such as to discourage any one really acquainted with the circumstances. The library had been full to bursting for two or three years and all attempts to get any more space, even temporarily, had failed. The personnel was about one half what it should have been for satisfactory prosecution of the work. The war was coming on, the demands of which could not be foreseen. There was little or no room left for accessions and none whatever for expansion of personnel. Moreover, there was such a scramble for space in the city of Washington that the library had no chance of securing anything adequate. It is not too much to say that the Army Medical Library was facing disaster then, for it could not long operate under the conditions prevailing. In addition, the books had for some time been deteriorating, even the modern ones, and the condition of the old books to the number of more than a thousand was deplorable. An attempt had been made a year or two before this to do repair work on the building, but by law it could be done only in emergency, and there were so many things to be done that the library was not able to do more than the necessary repairs. The library was in a state of disrepair and the conditions that were

of 1942 were a momentous one for it. The great institution was in its last days and some of its life and some of its history. Fortunately the war was not only possible but

PRESENT WAR
The Army Medical Library made with an opportunity actually in existence. The library had never been adequately modernized. Its setup modified by Congress, tempered with the who succeeded in the attempt to organize the personnel.

or the power seems far fetched, and for that reason it was done only on paper, to be put in operation when the new building was ready for occupancy.

The war the necessity for increasing the staff to take care of wartime needs and the utter inability to function fully in the cramped quarters enabled, indeed forced, the Surgeon General and the librarian to take long needed action. This consisted in an immediate reorganization of the staff and the method of operation, and to effect this it was necessary to move a part of the library to another city, not only for safety, but for the ultimate preservation of the books which had suffered so severely by attrition and lack of proper housing.

It was decided that a simple and logical method of operation should be devised as a guide based on experience and on future objectives. First, the old manner of operation was studied in graphic form. This appeared so unsound, showing as it did overlapping activities and utter lack of responsibility devolving on those who should have exercised authority in key positions, that the need for a new setup seemed the more urgent.

We asked ourselves: What did the library do, in plain and homely terms? The answer was that it searched for medical literature, it acquired and paid for it, it then indexed, catalogued and printed it, it bound the serials and it shelved or boxed the material, making it available for use through loan or otherwise. There were other things, however, that made the machine less simple than it appeared at first sight. There were the problems of administration, of conforming to War Department directives, of abiding by Civil Service rules and departmental rules, of securing funds each year from Congress, and so on. Finally, it seemed to us that the library ought to have four divisions and that all its activities must be made to fit into these divisions. The divisions were to be the Administrative, the Accession and Supply, the Index-Catalogue and the Circulation and Reference.

The Administrative Division is to be headed by a commissioned officer, the assistant to the librarian. This division handles all matters of personnel, discipline, police, fire control, mail and correspondence, liaison, orders and memorandums, staff meetings, repairs, finance, pay rolls, building and messenger service, utilities and so on. Its force is entirely clerical and fiscal and has no professionals in it. The largest subdivision is the Photoduplication Section, in reality almost an independent unit.

The next division is the Accession and Supply, and it is concerned with searching the markets of the world for medical literature. It corresponds in most of the modern languages if this is necessary. It buys current books and journals, checks files for completion, binds journal files at the end of a year, accessions books and pamphlets, sending them to the Index-Catalogue Division as they are received. The division is also charged with binding and rebinding, which is done at the Government Printing Office in Washington or, in the case of the Cleveland branch, at Cleveland binderies under negotiated contracts.

The third is the Index-Catalogue Division. It indexes and catalogues according to author and subject, all medical literature, portraits, broadsides, curios and the like coming to the library by purchase or gift. It is charged also with the production of the *Index-Catalogue*, which is published by the Government Printing Office. It does bibliographic research which is not ordinary reference work. The chief of this division is the editor of the *Index-Catalogue*.

The Division of Circulation and Reference, the last of the four, is concerned with direct service to the public. This means the jurisdiction and service of reading rooms, reference library, special collections, loans stack and reference service and related correspondence. Its main subsections are the main reading room, the journal room, the reference library and the document section.

The entire personnel in the library is now about sixty-four, although there is a considerable turnover owing to separations from the service, or one cause and another, and it is seldom that there are that many on duty for the reason that replacement causes long delays. As a rule, persons assigned to divisions of the library are not shifted to other divisions except when there is an urgent reason.

A few years ago the total personnel in the library was only thirty, and of these only four or five had a professional rating, all the others being clerical or sub-professional, no matter what their duties happened to be. Outside of the editor of the *Index-Catalogue* and one other person engaged in indexing and checking medical literature there was no one with a rating higher than a professional-1, which is the lowest professional grade. At the present time the employees who have a Civil Service rating have more than doubled, but the most noticeable thing is not the increase in number but the increase in the professional grade. Whereas once the professionals were but about 10 per cent of the total there are now fourteen employees with a professional rating, which is more than 20 per cent of the whole.

CLEVELAND BRANCH OF THE ARMY MEDICAL LIBRARY

The Cleveland branch of the library was established in July 1942. A considerable portion of the Allen Memorial Medical Library in Cleveland was leased for eight years, and this included unused air conditioned stack space to house fifty thousand volumes. It also included a former museum space which was cleared and turned over to the Army for conversion into library space. This will accommodate forty thousand volumes, the grand total being ninety thousand. Almost the entire Rare Book Collection of the Army Medical Library was sent by express in boxes to Cleveland to the number of about twenty thousand. This included all the incunabula, the works of the sixteenth, seventeenth and eighteenth centuries and a few other items but did not include nineteenth century works no matter how rare these happened to be. The incunabula had been kept together in the Army Medical Library as a unit only within the last four years. The sixteenth century works were scattered through the library shelves, apparently according to subjects. The editor of the *Index-Catalogue* and the librarian gathered the incunabula and the sixteenth century authors into a very nearly complete collection which was maintained on certain shelves. When the library was moved it was necessary to search the entire building for the other works of the seventeenth and eighteenth centuries which number more than fifteen thousand. This was a tremendous task, and it was useless to attempt to collect them in any sort of order. Accordingly the titlepage of every rare book was photographed before the book was packed. Finally the entire twenty thousand odd volumes were shipped to Cleveland to be unpacked and placed in order on the shelves.

The librarian has made arrangements with a Cleveland binding firm to start the great work of repair and rehabilitation a work which will take from three to five

years. It will require a large appropriation. No matter what the cost is, it will be worth it, for there is no such medical collection in the world and it will be possible, even now, to restore the collection and place it not only in as good condition as when the library first acquired the books but in a far better one. The work requires the attention of the best of experts, it includes matching old leather, the repair of parchment, careful cleansing, the restoration of damaged pages and the restoration of silver and leather clasps and thongs. The acquisition of the branch library in Cleveland for a period of eight years was the result of my complete and undeviating opposition to burying this collection in the ground for the duration, which was at one time suggested.

In addition to the Rare Book Collection, the Document Section of the library and a part of the Vital Statistics Section also have been removed. It is intended to keep up the service in the Cleveland library more or less in the same manner as in the Army Medical Library. The personnel in the branch library consists of an officer in charge, a curator of the rare books, two professional librarians, a chief clerk and an assistant and a messenger. Its staff is 50 per cent professional. In time, in the next few years, perhaps it will become the Mecca of those who wish to consult these rare treasures. Working space is available and every consideration will be given to those who are qualified to take advantage of their opportunity.

Naturally it will be inquired: What is the principal library work which is connected definitely with the war? There is greatly increased reference work for military and naval hospitals and medical activities. Our bibliographic and reference work is increased many times. We are helping war plants and factories in this field. Greatly increased information service is being requested by military personnel in Washington.

There is a constant search being made for new medical material in journal, in book and in pamphlet form published in Latin America. The library is securing all European medical material available in film form and is cataloging it and making it available for distribution. There is a great increase in photoduplication work for overseas units, for Free China and for the United Nations. Up to the present the Army Medical Library has turned out millions of pages of this medical material and is shipping overseas more than half a million pages a month. This is in the form of journal literature, of which about seventy complete titles are copied as they appear monthly as continuing orders and in book form. More than one hundred complete textbooks have been reproduced in film and sent to fifteen medical centers in China. This requires the master film to be copied fifteen times.

The library has been active in developing simple hand viewers for microfilm and in helping to place them on the market at a low price. Thus far three types have been modeled to sell at a nominal price.

The library does not limit its services solely to the Army and Navy requests but serves the medical public in every way possible. Its loans go to every state in the Union and its photoduplication service goes all over the world, to remote places in Canada, to the naval station in the Caribbean, to Australia and to Africa. Oftentimes we do not know where it goes, for the address is only a numbered American Post Office.

The work done for the Military Information Division of the Surgeon General's Office is constantly on the increase. The library is also assisting in the preparation of the Medical History of the War.

These are but the main types of work, but the demands made on us can hardly be limited, and each week brings new questions and new problems. During all this, the production of the *Index-Catalogue* goes on regularly, and the library also places its facilities at the disposal of the "Current List of Medical Literature" issued each week by the "Friends of the Army Medical Library" and the Medical Library Association.

THE FUTURE OBLIGATIONS OF THE LIBRARY

Among the many projects outlined by the Fine Arts Commission of the District of Columbia in connection with postwar plans for the development of the city of Washington, a new Army Medical Library and Museum occupies a prominent place in the \$400,000,000 program. The Fine Arts Commission has listed as its first item the development of East Capitol Street from the National Capitol eastward to Anacostia. This will result in a great central composition at least 5 miles in length. It will be excelled in this respect by no other capital city in the world. All the buildings along East Capitol Street are to be in either marble or granite similar to the Folger Shakespearean Library and, as the commission is careful to add, "the proposed Army Medical Museum and Library Building." Thus it would seem that eventually the Army Medical Library will come into its own and hope need no longer be deferred.

In order to do full justice to the new building in so prominent a location and to secure the funds for its erection, a careful estimation will be required concerning the usefulness of the library from a national standpoint, not only now but in the future. It is my belief that the library, with a closer relationship to the Library of Congress, with the retention of its freedom as a separate unit, will give us an institution deserving of the confidence it has enjoyed in the past. Lest it should be forgotten, we should remember that the Army Medical Library has a pleasant and profitable relationship with its sister institution, the Army Medical Museum, and that the fortunes of the two are closely linked and that they will march together in future years bound by common ties of mutual respect and helpfulness.

Among the many things that the library will face will be the task of distributing its enormous duplicate collection, acquired by gifts over a period of many years and now stored in hundreds of boxes, to institutions in various parts of the world which are most in need of it. The future relation of the library with the medical schools of the city of Washington must be carefully considered. Complete and satisfactory service will involve remaining open at night, as is now the practice of the Library of Congress. No doubt such a service should be given by the Army Medical Library. Again, the great collection of medieval medical literature, within a few years to be completely restored, will be returned to the parent institution under a competent curator. The standard of our personnel is rising, but it is not yet what it should be, and greater attention should be paid to the employment of scholars and to those skilled in library technique.

How shall we determine a wise course for the future, with definite commitments in the years to come and how shall we convince the lawmakers that a definite policy as to future operation and support can be agreed on? It will be apparent that this can be determined best by putting a number of heads together, and this brings up the last thing of importance for us to consider—the survey of the Army Medical Library by one of our national foundations. This has already been

arranged for, and it should begin within a few months, since the director and his staff have been appointed. The scope of this survey is broad. It will be a fact finding body which will submit constructive criticism with a plan for the future. It will consider the previous history of the Army Medical Library through its one hundred years of existence, the support that has been given it, its personnel, its method of operation and so on.

With the completion of this survey, it will be unnecessary in future to weigh various policies and recommendations that have been made at one time or another, many of them entirely out of date and not in keeping with modern library practice. Finally, it may be said that the vicissitudes and discouragements through which the library has passed will aid us to secure greater efficiency and a better future for this century old institution.

DIPHTHERIA MORTALITY IN LARGE CITIES OF THE UNITED STATES IN 1942

TWENTIETH ANNUAL REPORT

The procedure followed in obtaining data for this report is described in the review of typhoid mortality for these same cities.¹ Briefly, a communication was addressed to the health officer of each of the cities requesting the number of deaths from diphtheria both among residents and among nonresidents which were recorded in 1942. Inquiry was also made of the percentage of children under 5 years of age who had received a complete series of diphtheria protective treatments as of Dec 31, 1942. Such figure if available should give an approximate indication of the percentage of children who had received such treatment before entering school for the first time. In calculating death rates the 1940 census figures were used. The practice of charging all deaths, both among residents and among nonresidents against the individual city has been continued with the inclusion of appropriate symbols similar to those employed in previous years. Such symbols indicate those cities in which either (1) all diphtheria deaths were stated to be in nonresidents or (2) one third or more such deaths were stated to be in nonresidents. Attention is directed to tables 11 and 13, which together list forty-three cities (there were forty-five in 1941) which record no diphtheria death among residents in 1942. In addition to the thirty cities (there were twenty in 1941) with no diphtheria and typhoid deaths in 1942 (table 12), five cities (Birmingham, Dayton, Knoxville, Memphis, Utica) report no death among residents from either cause.

While most of the groups of cities report an increase in the number of deaths from diphtheria the New England cities (population 2,579,152) record the same total (eleven) for each of the two years 1941 and 1942 (table 16). This number is however, nearly double the total for 1940 (six). The rate remains the same (0.43). Of the eleven deaths it is stated that six were among nonresidents (four of these in Provi-

dence). Nine of the New England cities (Bridgeport, Hartford, Lynn, New Bedford, New Haven, Somerville, Springfield, Waterbury, Worcester) report no death from diphtheria in 1942. All nine were on the honor roll in 1941 except Springfield. Cambridge, with one death among residents, has lost its place on the honor roll which it held for the two previous years. Lynn has extended its good record to six years. New Bedford and New Haven to five years, Somerville and Waterbury to four years. Bridgeport and Worcester to three years. Lynn also reports no death from typhoid during the past six years. New Bedford has been free of deaths from the two diseases for five years, Hartford and Somerville for two years. Boston records two diphtheria deaths for 1942, one among residents (in 1941 there were three deaths, two among residents). Fall River reports two deaths among residents, Lowell two deaths, one among residents. Six of the eight New England cities (table 10) with no diphtheria death for two or more years report that from 50 (Waterbury) to 88 (Hartford) per cent of preschool children have received their protective treatments. Lynn, with no death for six years, records 71 per cent. New Bedford and Somerville could not provide adequate data. Boston and Fall River, with two resident deaths each, report only 15 and 18 per cent treated.

The eighteen cities (population 13,129,185) in the Middle Atlantic states (table 2) continue to hold first place and seemed to have very little competition in 1942. The number of deaths has increased from twenty-two in 1941 to twenty-three in 1942 but the rate remains the same (0.17). This maintains the new all time low rate established by these cities in 1941, approximated

TABLE 1—*Death Rates of Fourteen Cities in New England States from Diphtheria (Including Croup) per Hundred Thousand of Population*

	1942	1941	1940	1939	1938	1937	1936	1935	1934	1933	1932	1931	1930	1929	1928	1927	1926	1925	1924	1923	1922	1921	1920	1919	1918	1917	1916	1915	1914	1913	1912	1911	1910	1909	1908	1907	1906	1905	1904	1903	1902	1901	1900	1899	1898	1897	1896	1895	1894	1893	1892	1891	1890	1889	1888	1887	1886	1885	1884	1883	1882	1881	1880	1879	1878	1877	1876	1875	1874	1873	1872	1871	1870	1869	1868	1867	1866	1865	1864	1863	1862	1861	1860	1859	1858	1857	1856	1855	1854	1853	1852	1851	1850	1849	1848	1847	1846	1845	1844	1843	1842	1841	1840	1839	1838	1837	1836	1835	1834	1833	1832	1831	1830	1829	1828	1827	1826	1825	1824	1823	1822	1821	1820	1819	1818	1817	1816	1815	1814	1813	1812	1811	1810	1809	1808	1807	1806	1805	1804	1803	1802	1801	1800	1799	1798	1797	1796	1795	1794	1793	1792	1791	1790	1789	1788	1787	1786	1785	1784	1783	1782	1781	1780	1779	1778	1777	1776	1775	1774	1773	1772	1771	1770	1769	1768	1767	1766	1765	1764	1763	1762	1761	1760	1759	1758	1757	1756	1755	1754	1753	1752	1751	1750	1749	1748	1747	1746	1745	1744	1743	1742	1741	1740	1739	1738	1737	1736	1735	1734	1733	1732	1731	1730	1729	1728	1727	1726	1725	1724	1723	1722	1721	1720	1719	1718	1717	1716	1715	1714	1713	1712	1711	1710	1709	1708	1707	1706	1705	1704	1703	1702	1701	1700	1699	1698	1697	1696	1695	1694	1693	1692	1691	1690	1689	1688	1687	1686	1685	1684	1683	1682	1681	1680	1679	1678	1677	1676	1675	1674	1673	1672	1671	1670	1669	1668	1667	1666	1665	1664	1663	1662	1661	1660	1659	1658	1657	1656	1655	1654	1653	1652	1651	1650	1649	1648	1647	1646	1645	1644	1643	1642	1641	1640	1639	1638	1637	1636	1635	1634	1633	1632	1631	1630	1629	1628	1627	1626	1625	1624	1623	1622	1621	1620	1619	1618	1617	1616	1615	1614	1613	1612	1611	1610	1609	1608	1607	1606	1605	1604	1603	1602	1601	1600	1599	1598	1597	1596	1595	1594	1593	1592	1591	1590	1589	1588	1587	1586	1585	1584	1583	1582	1581	1580	1579	1578	1577	1576	1575	1574	1573	1572	1571	1570	1569	1568	1567	1566	1565	1564	1563	1562	1561	1560	1559	1558	1557	1556	1555	1554	1553	1552	1551	1550	1549	1548	1547	1546	1545	1544	1543	1542	1541	1540	1539	1538	1537	1536	1535	1534	1533	1532	1531	1530	1529	1528	1527	1526	1525	1524	1523	1522	1521	1520	1519	1518	1517	1516	1515	1514	1513	1512	1511	1510	1509	1508	1507	1506	1505	1504	1503	1502	1501	1500	1499	1498	1497	1496	1495	1494	1493	1492	1491	1490	1489	1488	1487	1486	1485	1484	1483	1482	1481	1480	1479	1478	1477	1476	1475	1474	1473	1472	1471	1470	1469	1468	1467	1466	1465	1464	1463	1462	1461	1460	1459	1458	1457	1456	1455	1454	1453	1452	1451	1450	1449	1448	1447	1446	1445	1444	1443	1442	1441	1440	1439	1438	1437	1436	1435	1434	1433	1432	1431	1430	1429	1428	1427	1426	1425	1424	1423	1422	1421	1420	1419	1418	1417	1416	1415	1414	1413	1412	1411	1410	1409	1408	1407	1406	1405	1404	1403	1402	1401	1400	1399	1398	1397	1396	1395	1394	1393	1392	1391	1390	1389	1388	1387	1386	1385	1384	1383	1382	1381	1380	1379	1378	1377	1376	1375	1374	1373	1372	1371	1370	1369	1368	1367	1366	1365	1364	1363	1362	1361	1360	1359	1358	1357	1356	1355	1354	1353	1352	1351	1350	1349	1348	1347	1346	1345	1344	1343	1342	1341	1340	1339	1338	1337	1336	1335	1334	1333	1332	1331	1330	1329	1328	1327	1326	1325	1324	1323	1322	1321	1320	1319	1318	1317	1316	1315	1314	1313	1312	1311	1310	1309	1308	1307	1306	1305	1304	1303	1302	1301	1300	1299	1298	1297	1296	1295	1294	1293	1292	1291	1290	1289	1288	1287	1286	1285	1284	1283	1282	1281	1280	1279	1278	1277	1276	1275	1274	1273	1272	1271	1270	1269	1268	1267	1266	1265	1264	1263	1262	1261	1260	1259	1258	1257	1256	1255	1254	1253	1252	1251	1250	1249	1248	1247	1246	1245	1244	1243	1242	1241	1240	1239	1238	1237	1236	1235	1234	1233	1232	1231	1230	1229	1228	1227	1226	1225	1224	1223	1222	1221	1220	1219	1218	1217	1216	1215	1214	1213	1212	1211	1210	1209	1208	1207	1206	1205	1204	1203	1202	1201	1200	1199	1198	1197	1196	1195	1194	1193	1192	1191	1190	1189	1188	1187	1186	1185	1184	1183	1182	1181	1180	1179	1178	1177	1176	1175	1174	1173	1172	1171	1170	1169	1168	1167	1166	1165	1164	1163	1162	1161	1160	1159	1158	1157	1156	1155	1154	1153	1152	1151	1150	1149	1148	1147	1146	1145	1144	1143	1142	1141	1140	1139	1138	1137	1136	1135	1134	1133	1132	1131	1130	1129	1128	1127	1126	1125	1124	1123	1122	1121	1120	1119	1118	1117	1116	1115	1114	1113	1112	1111	1110	1109	1108	1107	1106	1105	1104	1103	1102	1101	1100	1099	1098	1097	1096	1095	1094	1093	1092	1091	1090	1089	1088	1087	1086	1085	1084	1083	1082	1081	1080	1079	1078	1077	1076	1075	1074	1073	1072	1071	1070	1069	1068	1067	1066	1065	1064	1063	1062	1061	1060	1059	1058	1057	1056	1055	1054	1053	1052	1051	1050	1049	1048	1047	1046	1045	1044	1043	1042	1041	1040	1039	1038	1037	1036	1035	1034	1033	1032	1031	1030	1029	1028	1027	1026	1025	1024	1023	1022	1021	1020	1019	1018	1017	1016	1015	1014	1013	1012	1011	1010	1009	1008	1007	1006	1005	1004	1003	1002	1001	1000	999	998	997	996	995	994	993	992	991	990	989	988	987	986	985	984	983	982	981	980	979	978	977	976	975	974	973	972	971	970	969	968	967	966	965	964	963	962	961	960	959	958	957	956	955	954	953	952	951	950	949	948	947	946	945	944	943	942	941	940	939	938	937	936	935	934	933	932	931	930	929 ‡ Incomplete data

and Rochester in 1942. Utica, after seven years without a death from diphtheria, being dropped in 1941 because of a death in a resident adult, now returns to the select list. New York reports seven deaths all among residents (ten in 1941, ten in 1940). Philadelphia records three deaths, all among residents (three in 1941, two among residents). Pittsburgh has not maintained its 1941 low (five deaths in 1942, four among residents, one death among residents in 1941). Buffalo, Camden and Jersey City each report two deaths. Five of the six Middle Atlantic cities (table 10) with no diphtheria death for two or more years report that from forty-two (Yonkers) to ninety (Elizabeth, Newark) per cent of preschool children have received their protective treatments. Data are not available for Trenton. Utica with its excellent long time record reports 76 per cent treated. Four cities (Buffalo, Erie, Pittsburgh, Camden) report less than 40 per cent treated. Data are not available for New York, Paterson and Scranton.

In 1940 Charlotte was added to the nine cities previously included in the South Atlantic states (table 3) (population 2,727,985). The figures for this city have been omitted in the tables for group comparison. The

number of deaths in the original cities shows a definite decline (twenty-one in 1942, twenty-seven in 1941), especially among residents (thirteen in 1942, seventeen in 1941). The rate has decreased from 0.99 to 0.77. Wilmington is the only city on the honor roll. There were two such cities in 1941 (Charlotte, Miami). Two cities (Richmond, Tampa) report that all deaths were among nonresidents. It is stated that in three cities (Atlanta, Charlotte, Washington) one third or more of deaths were among nonresidents (two of six in Atlanta, two of four in Charlotte, one of three in Washington). Baltimore records two deaths, both among residents, Jacksonville, Miami and Norfolk each one such death. Baltimore and Norfolk report that more than 75 per cent of preschool children have received their protective treatments, Washington 39 per cent and Atlanta 24 per cent.

In obtaining data for the cities of the East North Central group (table 4), Gary (no death in 1942) has been included for the third time. The figures for this city have been omitted in the tables for group comparison. The cities of this group (population 9,386,378) report an increase of eight deaths (sixty-nine in 1942, sixty-one in 1941). The rate has increased from 0.65 to 0.73. The number of deaths in Chicago increased by nine (forty-three in 1942, thirty-four in

apolis for the first time reports no death from diphtheria It is stated that the one death in Wichita was among nonresidents St Louis reports six deaths, five among residents (there were but two in 1941) After a period of five years with no death, Des Moines reports one among residents Kansas City, Kan., and Kansas City, Mo., each record two deaths, the former two among residents and the latter one among residents Following a period of three years with no death among residents, St Paul records two such deaths in 1942 It is stated that in Des Moines, Omaha and St Louis 61 per cent of the preschool children have been treated Data are not available from the other cities

The eight cities of the West South Central states (table 7) (population 2,048,692) report an increase from thirty-four deaths in 1941 (forty-one in 1940) to thirty-nine in 1942 The death rate has increased from 1.66 in 1941 (2.00 in 1940) to 1.90 in 1942 While in 1941 50 per cent of the deaths (seventeen of thirty-four) were among nonresidents, in 1942 only one third (thirteen of thirty-nine) were so classified The deaths among residents have increased by nine, or 53 per cent No city appears on the honor roll It is stated that the three deaths in Fort Worth were among nonresidents Oklahoma City, on the honor roll in 1941, now records one death among residents In three cities (Dallas, New Orleans, San Antonio) it is stated that

one third or more of deaths occurred among nonresidents Three cities report rates in excess of 2.0 (Dallas, El Paso, Tulsa) Dallas records seven deaths, four among nonresidents, El Paso nine, two among nonresidents, Tulsa six, all among residents Houston reports six deaths among residents It is stated that 77 per cent of the preschool children have been given protective treatments in Dallas, 50 per cent in New Orleans, 36 per cent in Houston, 9 per cent in Tulsa Data are not available for the other cities in this group

In 1940 Sacramento was added to the eleven cities included in the Mountain and Pacific group (table 8) The figures for this city have been omitted in the tables

* The five following cities are omitted from this summary because data for the full period are not available Jacksonville Miami Oklahoma City, South Bend and Utica

† Data for Fort Worth lacking
‡ The rate for the ninety three cities in 1923 is 2.13 (population 37,025,179 diphtheria deaths 789) The corresponding rate for 1924 is 1.82 (population 37,241,414, diphtheria deaths 361)

Rate for ninety three cities in 1927 was 1.50 (population 37,450,000 diphtheria deaths 583)

¶ Rate for ninety three cities in 1938 was 1.26 (population 37,010,000 diphtheria deaths 477)

* Rate for ninety three cities in 1939 was 0.87 (population 37,540,000 diphtheria deaths 330)

¶ Rate for ninety three cities in 1940 was 0.60 (population 37,369,215 diphtheria deaths 225)

** Rate for ninety three cities in 1941 was 0.56 (population 37,569,215 diphtheria deaths 209)

*** Rate for ninety three cities in 1942 was 0.69 (population 37,769,215 diphtheria deaths 260)

†† 1940 census figures used

for group comparison The original cities (population 4,186,039) report a sharp increase in deaths (seventy-three in 1942, thirty-nine in 1941) The rate has increased from 0.93 in 1941 (the same in 1940) to 1.74 in 1942, which is higher than that reported by

any group of cities in 1941. The number of deaths among residents has doubled (fifty-four in 1942, twenty-seven in 1941). Long Beach is the only city on the honor roll. Tacoma, after being on the roll for two years, reports two deaths, one among residents. In four cities (Oakland, Sacramento, Seattle, Tacoma) it is stated that one third or more of deaths occurred among nonresidents. Three cities report rates of 20 or more (Denver, Los Angeles, Sacramento). Denver records twelve deaths, ten among residents (in 1941 eight, six among residents), Los Angeles thirty-one, twenty-one among residents (in 1941, twelve, four among residents), Sacramento eight, three among residents (in 1941 four, two among residents). In Los Angeles there has been an increase of seventeen deaths among residents. San Francisco reports five deaths among residents. San Diego three such deaths, Salt Lake City and Spokane two each. Of five deaths in Oakland, three were among residents, of four in Portland, three among residents, of seven in Seattle, four among residents. The health director of San Francisco states that four of the five deaths in his

* 1940 census figures used

city occurred in adults over 35 years of age. The fifth occurred in a child aged 2 years and 4 months who had been a resident of San Francisco for six months, nine months in the state. It is stated that 80 per cent of the preschool children have been given protective treatments in Oakland, 64 per cent in San Francisco, 50 per cent in Long Beach, 26 per cent in Seattle. Data are not available for the other cities.

Of the entire ninety-three cities there was one (the same city in 1941) with a rate in excess of 50 (table 14). The number of cities with no deaths from diphtheria has decreased by six (thirty-nine to thirty-three). The number of cities with rates below 50 has increased by six (fifty-three to fifty-nine). For the eighty-eight cities (table 15) for which data are available since 1923 there occurred two hundred and sixty deaths from diphtheria in 1942, significantly higher than for the past two years (two hundred and nine in 1941, two hundred and twenty-five in 1940). Is there to be a continued change in the trend? The rate, however, for this group of cities is for the fourth consecutive year less than 1.0. The rate for the ninety-three cities (0.69) is approximately the same as that for the eighty-eight cities (0.70). The actual number has increased by fifty (from two hundred and thirteen to two hundred and sixty-three). War travel may have been an influence in increasing the incidence of diphtheria, especially on the Pacific coast and in certain overcrowded industrial areas. Again lack of professional personnel may have slowed up the programs for protective treatments.

No explosive epidemics are reported by the health officers. The tendency for diphtheria to become relatively more prevalent among the higher age groups may be one explanation for the higher rates. It will be interesting to review the picture for 1943.

REPORT OF THE COUNCIL

THYMITARY NOT ACCEPTABLE FOR N N R

UNDER THE PROPRIETARY NAME THYMITARY A PREPARATION CONTAINING THE EXTRACTS OF THE THYMUS AND POSTERIOR PITUITARY GLANDS WAS OFFERED BY THE BLUE LINE CHEMICAL COMPANY FOR THE COUNCIL'S CONSIDERATION. THE COUNCIL AUTHORIZED A STUDY BY DR. JACOB SACKS WHICH ON THE BASIS OF ASSAYS OF THYMITARY SHOWED ONLY THAT IT HAD THE ACTION OF EQUIVALENT DOSES OF POSTERIOR PITUITARY EXTRACT. WITHOUT CONSIDERATION OF THE PROPRIETARY NAME THE COUNCIL DECLARED THYMITARY UNACCEPTABLE FOR INCLUSION IN NEW AND NONOFFICIAL REMEDIES BECAUSE OF IMPLIED OR EXPLICIT CLAIMS THAT ITS ACTION WAS DIFFERENT FROM THAT OF THE PHARMACOPEIAL POSTERIOR PITUITARY INJECTION. THE FIRM REQUESTED POSTPONEMENT OF PUBLICATION OF A STATEMENT OF THE COUNCIL'S CONSIDERATION UNTIL INVESTIGATIONS WITH A DEVICE CALLED THE LORAND TOCOPHAGU WERE COMPLETED. THE RESULTS OF THIS INVESTIGATION WERE FILED WITH THE COUNCIL TOGETHER WITH A CAREFUL STUDY BY DR. WILLIAM T. HYATT. THIS STUDY FAILS AS THE FIRM ADMITS TO ESTABLISH THE POINT WHICH IT HOPED TO DEMONSTRATE THAT IS A DEFINITE DIFFERENCE BETWEEN THE ACTIVITY OF ITS PRODUCT AND THAT OF THE U. S. P. POSTERIOR PITUITARY INJECTION.

THE FIRM HAS PREPARED A CAREFUL TABULATION OF THE PUBLISHED LITERATURE ON THE USE OF COMBINED EXTRACTS OF POSTERIOR PITUITARY AND THYMUS. PERUSAL OF THIS MATERIAL SHOWS THAT VERY FEW ATTEMPTS HAVE BEEN MADE BY EITHER LABORATORY OR CLINICAL INVESTIGATORS TO CONDUCT DEFINITELY PARALLEL TRIALS OF POSTERIOR PITUITARY INJECTION AND THE MIXED PREPARATIONS. THE COMPARISONS REPORTED FAIL TO DEMONSTRATE ANY ADVANTAGE FOR THE MIXTURE.

AS A RESULT OF THE FOREGOING STUDY THE FIRM SUBMITTED AN ADVERTISING CIRCULAR DESIGNED TO LIMIT THE CLAIMS TO ASSERTIONS WHICH COULD BE MADE WITHOUT QUESTION AS TO POSTERIOR PITUITARY ALONE. THE FIRM HOWEVER EXPRESSED ITS INTENTION OF CONTINUING TO MARKET THYMITARY. IN VIEW OF THIS THE COUNCIL VOTED TO PUBLISH FOR THE INFORMATION OF PHYSICIANS A STATEMENT CONCERNING ITS REJECTION OF THYMITARY AND THE FOLLOWING STUDY MADE FOR THE COUNCIL BY DR. JACOB SACKS.

AUSTIN E. SMITH, M.D., Secretary

THYMITARY

JACOB SACKS, PH.D., M.D.

AND ARNOLD MICH

THE USE OF THYMUS EXTRACT IN THE ATTEMPT TO MODIFY THE OXYTOIC OR POSTERIOR PITUITARY INJECTION IS BY NO MEANS NEW. A PREPARATION 'Thymophycin,' was introduced in Europe about fifteen years ago with the claim that the contractions resulting from its administration differ from those which follow the use of posterior pituitary injection alone in being rhythmic rather than tonic. On this basis it was claimed that Thymophycin could be used with safety to stimulate weak pains in the first stage of labor and to shorten the duration of the second stage. In the publication¹ in which this preparation was presented there was only the most limited evidence for such a modification of the action of posterior pituitary injection by thymus extract.

A thorough pharmacologic study of this preparation and of the effect of thymus extract on the pressor and oxytocic actions of posterior pituitary injection was made by Nelson.² He found that there was no difference which could be detected experimentally between the oxytocic and pressor activities of posterior pituitary injection alone and of a mixture of extracts of posterior pituitary and thymus. The pressor and oxytocic potencies of Thymophycin were found to be about one fourth to one third of those claimed on the label but when equivalent

¹ Thymophycin. A. Nelson, J. Thymus Extract in Labor and Its Practical Use in Obstetrics. Zentralblatt für Gynäk. 50: 22 (Feb. 1928).

² Nelson, E. E. Thymus Extract in Labor. J. A. M. A. 96: 52 (Jan. 31) 1931.

doses of posterior pituitary injection and Thymophysin were compared on excised uteri or on blood pressure no difference in action could be demonstrated. Thymophysin was declared unacceptable for inclusion in New and Nonofficial Remedies (THE JOURNAL, March 14, 1931, p. 860).

The dangers and limitations in the use of posterior pituitary injection in the first stage of labor are too well known to require any discussion here. They have been emphasized again in three recently published papers.³ The demonstration by Nelson that thymus extract does not modify the action of posterior pituitary injection would seem to have established that a mixture of the two has the same dangerous properties as the pituitary extract itself. It is established beyond question that posterior pituitary injection does increase the strength of contraction of uterine musculature. It is also well known that the clinical use of this preparation frequently results in an increased blood pressure.

The clinical literature on Thyntury is scanty, and pharmacologic studies are entirely wanting. There are brief reports by Wiesen,⁴ Cadwallader, Arthur,⁵ Hissong⁷ and Clemens.⁸ Wiesen used it in 50 cases of primary and secondary uterine inertia, Cadwallader in 110 cases of labor, Arthur reports 9 cases and Hissong 3. In all five papers it is stated that Thyntury shortens the duration of labor and does not lead to untoward results. Very few details are given, and in none of these brief reports are there any control observations which could serve as a basis for evaluating the preparation. In three of the papers there are expressions which are practically identical in wording with statements that have appeared in advertising matter which has been distributed by the promoters of Thyntury.

The present studies were undertaken to establish whether there is any difference in the actions of Thyntury and of posterior pituitary injection. Comparisons were made of the effects of the two in isolated uteri of guinea pigs and of rabbits, and of the pressor effects on the dog. The Thyntury used for these experiments was received in the original sealed packages. The standard posterior pituitary injection was made from reference standard powder obtained from the Board of Trustees of the U. S. Pharmacopeia and contained 2 units per cubic centimeter, the strength prescribed for assay purposes by the U. S. P.

Several assays of the oxytocic potency of Thyntury were made by the method of the U. S. P., and these showed that, within the limits of accuracy of this method, Thyntury contains 10 units per cubic centimeter, being therefore equivalent in potency to the official Injectio Pituitarii Posterioris.

With regard to the type of uterine contraction produced, it was found that there was no essential difference between Thyntury and posterior pituitary injection. In comparable doses the effects produced by the two were qualitatively and quantitatively the same. This was true for both guinea pig and rabbit uteri. In those cases in which posterior pituitary injection caused tonic contractions, Thyntury also produced this type of activity. Where posterior pituitary injection produced rhythmic activity, Thyntury also caused rhythmic contractions. From this it is clear that, so far as can be ascertained experimentally, there is no detectable difference between Thyntury and posterior pituitary injection with respect to oxytocic action.

Comparisons of the pressor activity of the two preparations were also made on pigs anesthetized with morphine and urethane, in which bilateral vagotomy had been done. Here again it was found that the pressor activity of Thyntury was equivalent to that of the official Injectio Pituitarii Posterioris,

and the character of the blood pressure rise was the same as that caused by the latter preparation.⁹

The results of these experiments are in agreement with those obtained by Nelson,² in which it was found that the addition of thymus extract to posterior pituitary injection did not modify in any way the pressor or oxytocic activity of the latter preparation. The clinical results that have been reported can all be accounted for on the basis of the known effects of posterior pituitary injection.

CONCLUSIONS

1 Assay of Thyntury by the method of the U. S. Pharmacopeia for posterior pituitary injection showed that it contains approximately 10 units per cubic centimeter and is therefore equivalent in oxytocic activity to the official preparation.

2 When equivalent doses of Thyntury and posterior pituitary injection were compared on isolated uteri of guinea pigs and rabbits, no differences in action could be demonstrated.

3 When equivalent doses of Thyntury and posterior pituitary injection were injected intravenously into anesthetized, vagotomized dogs, no differences in pressor action could be demonstrated.

The Council is of the opinion that the evidence in the foregoing report by Dr. Sacks indicates that Thyntury is, in effect, a preparation of the posterior lobe of the pituitary, and it appears that the firm's claims of any special activity of its preparation Thyntury are without adequate basis. Authorities in obstetrics agree that the administration of posterior pituitary injection in the first stage of labor is dangerous.

The Council therefore declared Thyntury (Blue Line Chemical Company) unacceptable for inclusion in New and Nonofficial Remedies.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

LACTATE RINGER'S SOLUTION (See New and Nonofficial Remedies, 1943, p. 462)

The following dosage forms have been accepted:

ELI LILLY & COMPANY, INDIANAPOLIS

Ampoules Lactate Ringer's Solution 25 Times Concentrated 10 cc and 20 cc. When 1 volume of the solution is diluted with 24 volumes of sterile distilled water, each hundred cubic centimeters of the diluted solution is equivalent in strength to lactate Ringer's solution-N. N. R.

PURIFIED SOLUTION OF LIVER (See Liver Injection, New and Nonofficial Remedies, 1943, p. 392)

The following additional dosage form has been accepted:

THE ARMOUR LABORATORIES, CHICAGO

Liver Liquid Parenteral, 15 U. S. P. Units per Cc 1 cc, 5 cc and 10 cc rubber capped vials. A sterile aqueous solution of liver, preserved with 0.5 per cent phenol.

SODIUM r-LACTATE ONE-SIXTH MOLAR (See New and Nonofficial Remedies, 1943, p. 461)

The following dosage forms have been accepted:

ELI LILLY & COMPANY, INDIANAPOLIS

Ampoules Sodium r-Lactate Solution One Molar 10 cc, 40 cc and 100 cc. Each 10 cc contains 1.12 Gm. of sodium r-lactate. Each 1 volume of this solution must be diluted with 5 volumes of sterile distilled water to obtain a sterile approximately isotonic solution equivalent in strength to sodium r-lactate one-sixth molar.

OVARIES (See New and Nonofficial Remedies, 1943, p. 398)

The following additional dosage form has been accepted:

THE LAKESIDE LABORATORIES, INC., MINNEAPOLIS

Ampule Solution of Estrogens (in sesame oil) 1 cc. Each cubic centimeter contains the equivalent of 20 (40) international units of estrone and 0.5 per cent of chlorobutyl alcohol as a preservative.

⁹ The Council office has on file the kymographic tracings of contractions and pressor responses in these experiments.

MEDICAL EDUCATION AND THE WAR

A Series of Articles by Federal Authorities Concerning the Medical Services of Wartime and the Selection and Training of Premedical and Medical Students

THE UNITED STATES ARMY AND MEDICAL EDUCATION

Major General Norman T. Kirk
Surgeon General U. S. Army

The Army Specialized Training Program explained more in detail elsewhere in this issue, is the result of planning for the future by the War Department. Recognizing that the present demands on the Medical Dental and Veterinary Corps will be definitely increased as the war continues, it is necessary to prepare for future eventualities before critical needs arise.

An announcement of the projected plan of the Army Specialized Training Program was made by the Commanding General Army Service Forces. This was followed by a meeting between the Council on Medical Education and Hospitals and the Surgeon General in Washington. It was the feeling at this meeting that subsidization of medical education had certain drawbacks but there were other considerations which outweighed these. It should be a source of pride to the medical profession that the educational program is carried to completion and a degree granted to graduates only in the case of physicians, dentists and veterinarians. Those soldiers attending engineering schools, electronics, physics and so on may not be granted a degree.

The recognition of the requirements of medically qualified graduates set the pace for mutual agreement and understanding of medical problems between the Council and the War Department. Many problems have arisen regarding the accelerated medical educational program. My office has had to seek the cooperation of hospitals and medical schools in the solving of some of these problems. The hearty response to any request leads me to express my deep appreciation to those members of the profession who have worked so unselfishly to make this planned program a success.

It was estimated early in the war that the planned army would require 63,000 physicians by the end of 1943. However, when the total number of physicians in the United States is considered, it is estimated by reliable sources that the Army will not be able to secure more than 48,000 without subjecting the civil

population to considerable hardship. Every position calling for a medical officer in the Army Ground Forces, Army Air Forces and Army Service Forces was considered in order to determine where the services of such officers could be done away with. As a result of this work we have developed an effective plan for the utilization of the 48,000 medical officers to give the best possible care to the members of the Army. A close study of assignments must be maintained at all times in order to utilize fully the professional abilities of the physicians and leave administrative work as far as possible to those not qualified as medical officers.

We must further consider the normal attrition of medical officers, which is similar to that in civilian life but augmented by the increased casualty expectancy of armed forces. In the recent African campaign the casualty rate was much lower than expected, owing to careful negotiations and prearranged plans between the leaders of the Allied Nations and the French government in North Africa. Such a state of cooperation cannot be expected in forthcoming activities on the European continent, and this will never be true in the Pacific theater of operations. It is obvious that the offensive role in this war will increase tremendously the casualty rate of both enlisted and commissioned personnel. This means that the present attrition of medical officers will assume higher proportions as a result of losses or wounded, prisoners of war, killed or missing in action.

The increased tempo of warfare in the Southwest Pacific will also add to the casualty rate in that theater of operations. With the battle fronts extending over every part of the globe the work of the Medical Department is assuming tremendous proportions and the strain, both mentally and physically, adds to the normal attrition of medical officers.

The augmented medical program will increase the number of available physicians per year. Of this num-

ber it is contemplated that approximately 55 per cent of the medical graduates will be necessary to maintain the strength of the Medical Corps at a properly functioning level (48,000). Assuming that 6,000 (plus) graduates are available each year, this means that 3,300 physicians will be needed as replacements in the Army. Our present figure for separations from the service has increased in 1943 over the figure of 1942. The average rate of separations from the service from all causes is approximately 35 per week. This will probably be increased to 45 per week within the next twelve months, or a total of 2,340 losses for the Medical Corps.

When we consider that at the present time 25 to 35 per cent of all applicants for commission are rejected by reason of physical disqualification alone, the figure 3,300 (representing an estimated 55 per cent of the yearly graduates of medicine) is just enough to provide the estimated replacements required in the Medical Corps, with a small leeway for adjustment. In other words, the War Department is faced with the absolute necessity of obtaining that number of replacements every year without regard to increasing the overall number of medical officers on active duty.

Thus we can see the necessity of a plan which will furnish the required physicians for duty with the Army. The Army Specialized Training Program embodies this program. Civilian medical care will not be depleted to the danger stage, since approximately 20 per cent of the graduates will be available for civilian replacements while many of those physicians separated from the service will be fully capable of carrying on an average civilian medical practice. One great danger in such a program lies in the postgraduate training of the individual physicians.

Present postwar plans are being formulated to combat this weakness and enable physicians to secure advanced training. After the war many physicians will decide to remain in the service, as happened in the past war, and no doubt will be privileged to increase their training by proper assignment to professional duties within the Army. Civilian hospitals and schools will be able to provide adequately for the advanced training of those physicians who return to civilian life. Close study of this program will show the need of cooperation between the members of the medical profession, both within and without the military service.

THE ARMY SPECIALIZED TRAINING PROGRAM

Colonel Francis M. Fitts, M. C.
Army Service Forces

A review of the problems of medical education during 1942-1943 cannot disregard those occasioned by the educational programs adopted by the Army and the Navy with a view to assuring for the armed forces an uninterrupted supply of young medical officers during the period of the national emergency. It is too early to judge results, possibly an early termination of hostilities may obviate the necessity of observing the operation of the more radical features of the program's departure from normal peacetime procedures.

In December 1942 the Secretary of War and the Secretary of the Navy, in a joint statement, recommended the utilization of college facilities in specialized training for the Army and the Navy. The objective of the Army program was announced to be "To meet the need of the Army for specialized technical training of soldiers on active duty for certain Army tasks for which its own facilities are insufficient in extent or character. To that end the Army will contract with selected colleges and universities for the use of their facilities and faculties in effecting such training of selected soldiers in courses prescribed by the Army."

The reason for this action is apparent: under existing conditions the constant and adequate supply of medical officers required by the Army as replacements for anticipated losses among those on active duty could not be assured. Established civilian sources are being rapidly depleted. Additional medical officers must be procured through the specialized training of potential physicians already in, or entering, the military service.

It was not considered practicable to continue the training of members of the military establishment in medicine and premedicine on a purely voluntary basis and on an inactive duty status. Since the facilities of the Army are not those required for the training of physicians, the Army Specialized Training Division of the Army Service Forces was requested to make the necessary arrangements for the selection and training of qualified enlisted men in medicine, and in the prepa-

ration for the study of medicine, in sufficient numbers to assure the loss replacements required to maintain an adequate medical service for the Army.

The same problem confronted the War Department in 1917. Provisions were imperative to guarantee the continued supply of physicians to the Army. The solution was quite analogous to that adopted in 1942 for the continuation of nonprofessional training, at the college level, of potential officer candidates: enlistment in the Enlisted Reserve Corps and deferment of call to active duty for the purpose of the completion of the academic preparation for military duties. On the establishment of the Student Army Training Corps in 1918 and the activation of units of that corps in colleges and universities throughout the country, the members of the Medical Department Enlisted Reserve were called to active duty and assigned to the Student Army Training Corps to pursue their professional studies in uniform. No provisions were made for premedical training as such or for selective procedures for assignment to Student Army Training Corps units at medical schools for the purpose of pursuing instruction in medicine, nor did the government assume the responsibility of paying for this specialized training. A month after the inauguration of the program the armistice was signed, and shortly thereafter the enlisted men of the Students Army Training Corps were discharged to return to their briefly interrupted studies.

In 1939, with the same end in view, the War Department approved measures whereby, during a national emergency, medical students then holding commissions in the Officers' Reserve Corps would not be called to active duty until after the completion of their professional studies. This was followed in 1941 by provisions for placing other medical students and premedical students accepted for admission to the next ensuing class in approved schools of medicine under Army jurisdiction. This was accomplished through their voluntary appointment in the Medical Administrative Corps. Their call to active duty has been deferred in order

that they may complete their professional training with a view to appointment in the Medical Corps, Army of the United States. Approximately 60 per cent of the students in these schools waived themselves of this opportunity to complete their medical education and accepted the obligation of future military service.

No similar provisions could be considered for premedical students whose admission to the study of medicine was not assured. However, under the general preinduction training program adopted in 1942 this group was permitted to enlist in the Enlisted Reserve Corps and, prior to the initiation of the Army Specialized Training Program were permitted to continue their studies on an inactive duty status. Those who had not been accepted for matriculation for future entering classes in medicine have been called to active duty. They are eligible for the resumption of collegiate training if selected for assignment to the Army Specialized Training Program at the completion of their basic military training thirteen weeks in duration. The probability of their resuming premedical studies, however, is no greater than that which they would have had of entering on the formal study of medicine in civil life.

The majority of the premedical students who were members of the Medical Administrative Corps or the Enlisted Reserve Corps and who have assured vacancies in medical schools through their formal acceptance for admission to future entering classes are continuing the premedical studies prerequisite to such matriculation on an inactive status at their own expense. Others have been assigned to Army Specialized Training units for the completion of their premedical training. Still others who have completed their premedical studies are receiving basic military training or are serving in military hospitals pending transfer to the Army Specialized Training unit at the institution by which they have been matriculated.

WOMEN NOT INCLUDED

It is anticipated that training in medicine under the Army Specialized Training Program will have been initiated by July 23, 1943 in all approved schools of medicine with the exception of the Woman's Medical College of Pennsylvania. It is not contemplated that the utilization of the facilities of this school will be requested or that female enlisted personnel of the Army will be assigned to the Army Specialized Training Program for training in medicine. Since women are not under the potential compulsion of Selective Service, their entrance into the military service is purely voluntary. There is no cause for either the interruption or the postponement of their medical education. The supply of women physicians should not be affected by the national emergency.

SELECTION OF MEDICAL STUDENTS

The assignment of enlisted men to the Army Specialized Training units at approved schools of medicine is, until further notice, restricted to those who are currently enrolled in, and to those who have been accepted by, such schools for future entering classes. This restriction of selection for the continuation of premedical training and assignment for professional training to the enlisted men for whom there are assured vacancies in a medical school is necessitated by the fact that freshman classes have been filled for 1943 the first half of 1944 and, in a number of schools, for late 1944. If these applicants are in, or enter, the active military service they will be assigned to the Army Specialized Training Program for the completion of prerequisite

premedical training and subsequent timely transfer to the Army Specialized Training unit at the school by which they have been accepted.

It is obvious, however, that medical schools cannot continue to fill their entering classes from civilian sources only. Many students contemplating or preparing for the study of medicine will have been inducted into one of the armed forces before acceptance by an accredited school is possible. Others will be unwilling to remain out of the military service for the purpose of preparing themselves for the study of medicine. If the supply of physicians not only to meet the requirements of the armed forces during the current emergency but also for postwar civilian needs is to continue beyond those now in or accepted for medical training, appropriate steps must be taken by the Army and by the Navy to assure necessary preparatory studies by qualified individuals in active military service with a view to subsequent training in medicine.

PREMEDICAL TRAINING

In order that detailed plans may be made for such premedical training under the Army Specialized Training Program the War Department is taking steps to determine the number of Army trainees who may be assigned to Army Specialized Training units at medical schools for instruction in future freshman classes. The program of the Army will require at least 55 per cent of the vacancies in medical schools. The possibility is being explored of a mutual agreement whereby carefully selected enlisted men, not accepted as individuals by the individual schools of medicine, may be assigned to fill these vacancies with a view to receiving the degree of doctor of medicine and to being appointed in the Medical Corps of the Army of the United States.

The procedures involved in the selection and training of the enlisted men whom the medical schools will be requested to train in medicine may be briefly outlined as follows:

On entering the Army the recently inducted soldier is given certain general classification tests, the results of which are entered on the record which accompanies him to the unit or installations in which he receives his basic military training. Those with certain high scores (115 or better on the Army General Classification Test) will then appear before Army Specialized Training Program field selection boards to determine whether they should be assigned to this program for training at the college level. The actual field of such training and the academic level at which training should begin will be determined at the classification and assignment units to which these selected soldiers are first assigned (Specialized Training and Reassignment unit referred to as a STAR unit).

From the STAR unit candidates who are manifestly suitable for or interested in the study of medicine will be transferred to appropriate training units to begin premedical studies at the basic level. The premedical curriculum in the first two terms, of twelve weeks each, is common to that followed by trainees tentatively selected for engineering specialties. This basic curriculum includes mathematics, physics, general chemistry and English, as shown in the accompanying table. Descriptions of the courses listed are available from the Army Specialized Training Division.

It is during the second term that the real selection for premedical training is to be made for subsequent training in medicine. Representatives of all the approved schools of medicine will participate in this

selection. It is on them that the War Department is depending for expert advice in determining the enlisted men who should receive training in premedicine. Since premedical training is, per se, of little value in the military service, attention must be held to a minimum. At this level trainees not considered fully qualified, especially as regards fitness and aptitude for and attitude toward the study of medicine, appointment in the Medical Corps of the Army of the United States and the practice of the profession of medicine in civil life, may be considered for other fields of specialized training under the Army Specialized Training Program.

Outline of Army Premedical Curriculum

Subject		1st Term	Required Distribution	
			Class	Laboratory

^a Required by contract

* One hour for writing reports

^b 1 French, German, Spanish for students who have studied one of these in high school or college—must continue in 5th Term

2 Economics—must continue in 5th Term

3 Public administration

4 Quantitative analysis

5 Physical chemistry

The trainees selected for future training in medicine begin their biologic studies in the third term and continue them through term five, the last term of the premedical curriculum. Organic chemistry and psychology are added in the fourth and fifth terms. In these two terms eight semester hours are available for subjects selected by the institution based on the interest and special aptitude of the trainee. This will permit a brief refresher course in a modern foreign language for trainees who have had appropriate previous instruction. It has not been considered possible to include a language as a prescribed subject to the exclusion of other universal requirements.

While it is felt that the complete task of preparing physically qualified male students for the study of medicine will devolve principally on the Army and the Navy, it is certain that premedical students will continue to enter the military service at various academic levels. At the completion of their basic military training these enlisted men must be given serious consideration for the continuation of their premedical training and subsequent training in medicine under the Army Specialized Training Program. The selection of these enlisted men for such training will be made at STAR units if they are to be assigned for premedical studies in terms above the second. This selection must be conducted with the same care as—indeed even greater care than—in the case of trainees who are assigned to the Army Specialized Training Program at the basic level. Separate curriculums designed to complete premedical training previously begun in civil life have been arranged for these trainees.

The progress of the premedical trainee will be checked both by the usual faculty examinations and by periodic nationwide Army tests. The enlisted men who satisfactorily complete the premedical curriculum will be considered available for transfer to Army Specialized Training units for training in medicine or dentistry.

Such assignments must necessarily be governed by timely regional vacancies. The Army trainee will not make application for admission for the study of medicine, nor will he be accepted as an individual for a class in which vacancies are reserved for the War Department. His general fitness and acceptability for the study of medicine have been determined. If recommended at the completion of premedical training, he will be academically qualified. If it is proved that he cannot continue satisfactory progress in his medical studies, he will be relieved from the Army Specialized Training Program for assignment to other duties.

Because of the necessity of assigning Army trainees to fill vacancies which have been reserved for the War Department on a strictly numerical basis, rather than by name, no assurance can be given that individual students accepted for classes in which reservations have been specifically made for the Army will be assigned to the Army Specialized Training unit at that school. It is realized that such a policy will limit the personal selection of medical students which has proved so satisfactory and successful in previous years.

The question of individual assignment has been given careful consideration by the War Department. Measures designed to place trainees in medical schools best suited to their abilities and their possibilities for development, or to avoid assignment to particular environments for which the trainee appears unsuited, must necessarily be not only preferential but also prejudicial in character. They would also open the door to unlimited political pressure and universal dissatisfaction. No plan for individual selection and assignment appears feasible.

The transfer of medical trainees from one unit to another is not contemplated, except, of course, in the case of those who have successfully completed their instruction in the schools of the basic medical sciences. It is felt that such trainees may advantageously be transferred as individuals, and to this end it has been requested that arrangements now in force between the deans of the various approved schools of medicine be continued.

Negro enlisted men qualified for medical training will be assigned to fill vacancies reserved for the War Department at Howard University and Meharry Medical College.

The preceding paragraphs present a brief outline of the general plan of medical and premedical training under the Army Specialized Training Program. The adaptation of the general Army program to the existing scheme of medical education has necessitated modifications in War Department directives governing the selection and assignment of trainees and the academic curriculums and schedules under which the training of military personnel is conducted by individual institutions other than schools of medicine, dentistry and veterinary medicine.

As previously stated, medical training under the Army Specialized Training Program consists of two distinct phases: a premedical phase of five terms of twelve weeks each with one week interlough between terms and a medical phase which conforms to the accelerated program of medical education adopted by the several schools on the recommendation of the Council on Medical Education and Hospitals of the American Medical Association and by the Association of American Medical Colleges.

THE CURRICULUM

No change is desired in the standard curriculum under which the individual medical school has been teaching medicine. However in view of the wide variations in premedical curriculums it has been necessary to formulate one which will be followed in the colleges and universities in which Army trainees will be prepared for its logical sequel, the study of medicine. Careful selection of the enlisted men who are to receive premedical instruction will reduce the enormous wastage which unfortunately has characterized collegiate preparation for the study of medicine.

Premedical training will conform to the daily, weekly and term schedule prescribed for all other Army Specialized Training. Preliminary basic military training,

group housing and messing, military instruction, physical training and supervised study will assure that such trainees be and continue to be soldiers in fact, not in name only—soldiers in college, not students in uniform. The military aspect of the program, however, is secondary to the academic in the premedical as well as in the medical phase.

In the latter, for the time being, Army trainees will unfortunately be at a distinct disadvantage—they will have had little or no preliminary military instruction, they may fail to realize that they are soldiers, with all the responsibilities of a soldier as well as the prerogatives. Only in the exceptional cases in which facilities for group housing and messing are available at the individual institution will medical trainees live in dormitories. They will nevertheless be under careful military discipline and control. They are assigned to a definite unit and detailed to the study of medicine. The satisfactory pursuit and completion of such studies is their military duty, their contribution, at this time, to the successful prosecution of the war.

The prescribed military instruction of medical trainees has been reduced to that hitherto required in medical units of the Reserve Officers' Training Corps. Physical training is not mandatory. It is hoped, however, that satisfactory arrangements may be made at each school for their maintenance in creditable physical condition. This will certainly contribute to the academic progress of the trainee.

On graduation the trainee will be discharged from his enlisted status in order to accept a commission in the Medical Corps, Army of the United States. He will not, however, be ordered to active duty as an officer before the completion of twelve months hospital internship on an inactive duty status. Arrangement for such internships must be made, as in previous years, by the individual trainee.

On completion of the internship the young officer will be ordered to active military duty. He has completed his specialized training, he is now ready and prepared for service.

THE UNITED STATES NAVY AND MEDICAL EDUCATION

Rear Admiral Ross T. McIntire
Surgeon General U S Navy

The Navy V-12 Program as it relates to medical education went into operation on or shortly after July 1 in sixty-four approved medical schools throughout the nation. The medical schools have the important responsibility of offering medical education of the highest quality to the students assigned them and of helping these students put forth their best efforts so that the Navy and the country will have a continuous reservoir of outstanding medical officers to meet the needs of the service and of the civilian postwar period.

The ultimate goal of the medical phase of the Navy V-12 Program is to insure a constant flow of medical officers for the naval service, to give these prospective naval doctors the benefits of the very best medical education and, while doing this, to preserve the normal pattern of medical school life and to safeguard the scholastic integrity and identity of medical education. The medical schools are not asked or required to change their curriculums or methods of teaching and are not asked to lower their high standards. It is the Navy's responsibility to defray the cost of the student's educa-

tion and the school's responsibility to give this education unhampered.

The students assigned to schools will have been found morally, physically and intellectually fit to enter medical education as the result of a previous thorough screening by the Navy in cooperation with the deans or their representatives. The Navy will accept the recommendation of the school for withdrawal of a student for scholastic failure, inaptitude or other sufficient reason.

It is believed that this program will not alter medical education or have a deleterious effect on the student and tutored doctor by way of softening him, robbing him of his initiative or destroying for him the satisfaction experienced by previous students in medical schools who obtained their education through their own endeavors.

The faculties of medical schools already depleted by many members having joined the armed forces will be heavily burdened with extra teaching responsibilities, owing to the accelerated teaching program and increased enrolments. It is hoped that they will be able to main-

tain the same degree of efficiency, vigor and cheerfulness of other years.

The Navy desires the schools to reserve at least 25 per cent of the enrollment of entering classes in each medical school for the Navy premedical students. The contract with medical schools provides for the payment of tuition, laboratory fees, rental of microscopes, other required equipment and the utilization of the existing Student Health Programs. Not more than one textbook in each subject in which a textbook has previously been required by the faculty of the school will be paid for by the Navy and assigned to each student. This textbook will remain the property of the student while he remains in medical school.

The Navy medical student is classified as an Apprentice Seaman, Class V-12(S), U. S. Naval Reserve, on active duty, receiving the pay and allowances of this rate, also a per diem allowance in lieu of subsistence and quarters. He will wear a uniform similar to the Midshipman's uniform with an appropriate insignia and thin gold stripes on his sleeve to designate his class. It is not intended that the student be required to take time away from his normal course of studies for military drills or indoctrination courses. Although in the other V-12 Educational Units physical training is compulsory, it will not be required of medical students. However, it is my fervent hope that the medical student will carry out a voluntary program of physical exercise, swimming and similar conditioning exercises as often as the opportunity presents, so that when he is assigned to active service as a doctor his physical tone will be comparable to that of the other officers and men with whom he will be serving.

A medical student is not prohibited from marrying while he is in attendance at medical school. If he fails to maintain satisfactory standards he will be assigned to other duty for which qualified. A senior medical student may accept externships if the externship is approved by the dean and is given credit by the school, and if the student receives no financial remuneration

for it. The medical student will continue to seek an internship, as has been the practice in the past. He may either contract for civilian internship or make application for examination for appointment as Acting Assistant Surgeon for internship in the Medical Corps of the U. S. Navy. On satisfactory completion of his medical education he will be commissioned Lieutenant (junior grade) MC-V(G), U. S. Naval Reserve, and placed on inactive duty for the purpose of attending his internship or, if qualified and selected, will be appointed Acting Assistant Surgeon in the Medical Corps of the U. S. Navy and assigned to active duty in a U. S. naval hospital for his intern training. Internships will be of twelve months' duration.

As a result of the Navy's assumption of all the financial obligations for the student's medical education, the payment of a salary plus allowances, the provision of full medical care and hospitalization when sick, there should be fewer scholastic failures, an upswing in scholastic attainments and a physically and emotionally healthier student. The type of military uniform worn by the medical student is in keeping with his scholastic seniority and the kind of education pursued. Being in uniform will protect the student from unwarranted criticism and help to combat and ameliorate the restless, unpleasant feeling that young men of this age group have experienced, that is, the impatience at not being more actively engaged in and directly identified with the armed services.

The medical student who, because of a physical handicap, has not been selected to participate in the Navy's Medical Educational Program, should not develop feelings of inferiority or have a feeling of not belonging to an organization, for he is being educated to serve in a medical capacity which is as important as that of his classmate in uniform.

I feel confident that the Navy's alliance with medical schools for the training of needed medical officers will be successfully accomplished in mutual cooperation and respect and concluded with great benefit to both.

THE NAVY PREMEDICAL PROGRAM

Commander B. W. Hogan (MC)

Bureau of Medicine and Surgery Navy College Training Program

The Navy V-12 Program, which became effective on July 1 with units established in one hundred and thirty-one colleges and universities and in approved medical and accredited dental schools throughout the nation, is designed to protect the source of officer candidates and to produce a continuous supply of officers for the several branches of naval service.

Undergraduate V-12 units, eighty-nine of which include quotas of premedical students, conform to certain general policies and regulations. The students live in college dormitories and fraternity houses, selected and approved by the Navy, eat together in Navy messes, follow curriculums prescribed in full or in part by the Bureau of Naval Personnel and, except for members of the N. R. O. T. C. and men enlisted in Marine Corps Reserve, Class III(d), are uniformed as apprentice seamen. All students in the V-12 Program, including medical and dental students, receive the pay and allowances of apprentice seamen on active duty.

The primary purpose of the Navy V-12 Program is education. Military discipline and procedures are

kept to a minimum consistent with the successful operation of a naval activity, as most V-12 students will receive specialized naval training later while attending the indoctrination schools or in naval training schools. Hence the undergraduate phase of the V-12 Program, by preserving, so far as possible, the normal pattern of college life, protects premedical students in the early stages of their education, permitting them to pursue their studies without undue distraction.

There are approximately 6,500 Navy premedical students assigned to eighty-nine universities and colleges throughout the country. They are scattered through the various years of premedical education. The premedical students for the V-12 Program were selected with procedures similar to those used for other students. Students who entered the program on July 1 came from three sources.

1. The enlisted reserves constituted the first group. These were enrolled in the premedical curriculums in colleges and universities approved for the V-12 Program. The members of this group who were near the end of their fourth semester of work or who had com-

pleted four or more semesters were given a comprehensive achievement examination late in April. Students standing in the lowest 10 per cent of the distribution of scores on this examination were eliminated. The remaining students were permitted to continue with their premedical courses or to enter a medical school, provided they were accepted for admission.

2 The second group of students came from among the enlisted men in service. These students were selected on recommendation of their commanding officers provided they had attained a specified minimum score on the General Classification Test.

Outline of Navy Premedical Curriculum

First College Year	Credits per Week	
	1st Term	2d Term
Chemistry I II (C1 2)	4 (6)	4 (5)
Physics I II (III 2)	4 (6)	4 (6)
Mathematical analysis I or III II or IV (III or 2 or 4)	5 (5)	5 (5)
Modern foreign language III (III 2)	3 (3)	3 (3)
Naval organization I II (NI 2)	1 (1)	1 (1)
Physical Training	17 (21)	17 (25)
	35 (91½)	34 (91½)
Mathematical Analysis I and II combination course in mathematical analysis for students entering with 2 or less units of mathematics. Mathematical Analysis III and IV algebra, trigonometry and analytic geometry or analytic geometry and calculus for students entering with 2½ or more units of mathematics.		
Second College Year	Credits per Week	
	1st Term	2d Term
Chemistry III quantitative analysis (C3)	4 (5)	
Organic chemistry I (C4)		4 (8)
Biology I II (BI 2)	4 (8)	4 (8)
Modern foreign language III IV (I 3 or)	3 (3)	3 (3)
English III (EI 2)	3 (3)	3 (3)
Historical background of present war III (III 2)	2 (2)	2 (2)
Psychology I general (PS1)	2 (2)	2 (2)
Physical training	18 (26)	18 (26)
	35 (91½)	35 (91½)
Third College Year	Credits per Week	
	1st Term	2d Term
Biology III (embryology or Biology IV comparative anatomy) (B3 or 4)	5 (9)	
Organic chemistry II (C5)	4 (8)	
Modern foreign language V or VI (L5 or 6)	3 (3)	
Psychology II abnormal (PS2)	3 (3)	
Elective	3 (3)	
Physical training	18 (26)	17 (81½)
	35 (91½)	34 (81½)

Figures in parenthesis indicate contact hours per week in class and laboratory. Figures outside parenthesis indicate the number of meetings per week in class and laboratory.

3 A third group of students were selected directly from civil life. These were chosen in terms of a rigid screening procedure which included (a) a scholastic aptitude test given at approximately eighteen thousand centers throughout the country, (b) a physical examination, (c) an interview by a naval officer in the Office of Naval Officer Procurement and (d) final selection by a committee of three, including a naval officer, a business man and an educator. This committee considered all the information available on each applicant. From those finally selected for the V-12 Program, only the highest ranking students with a preference for premedical training were admitted to the premedical curriculum.

Further screening of premedical students will be done on the basis of scholastic records and comprehensive achievement examinations. An achievement examination similar to that given late in April of this year will be given to other students from the V-12 group during the fourth term of work. Also students entering the prescribed premedical curriculum directly from civil life will be given an achievement examination near the end of their first two terms. Final selection of students for medical schools will be made in cooperation with the medical schools on the basis of these records. The details of this procedure are to be completed in the near future.

The premedical curriculum was worked out on the basis of past practices in colleges and universities and has the wholehearted approval of the Council on Medical Education and Hospitals and the Association of American Medical Colleges. It is generally believed that it represents the best type of premedical education that has been offered at colleges and universities. It extends over five terms of sixteen weeks each, a total of twenty months of premedical preparation. A detail outline of the curriculum is presented in the accompanying table. Course descriptions are given in detail in Bulletin No. 1 "The Navy College Training Program V-12, Curricula Schedules" issued by the Training Division of the Bureau of Naval Personnel of the United States Navy, Washington, D. C.

The method of selecting the qualified premedical student for medical education and his assignment to a medical school is as has been stated not yet finally determined. The proposed plan is to assign students to medical schools within the naval district where they are at present pursuing premedical education. A committee of the deans or their representatives of the medical schools in a naval district would select from the premedical students in that district who are finishing their preprofessional training those who are qualified for admission to medical school. These successful students would then be assigned by the Navy Department to fill the Navy's quota in the medical schools of that district. There might be in some naval districts a surplus of well qualified premedical students, and in other naval districts there might not be a sufficient number to fill the Navy's quota in the medical schools of that district. In these instances it is the suggestion of the Navy that a reciprocity agreement be established between naval district screening boards in order to fill existing vacancies with Navy premedical students found qualified by screening boards in other areas.

Premedical students who have been accepted for admission to an approved medical school and have several months to wait before matriculating in medical school will be assigned to naval hospitals under instruction in the laboratory fields of medicine and in addition at certain hospitals they will assist the educational officer in the Navy's Hospital Educational Program for convalescent patients.

I am quite sure that, from the standpoint of both selection of students and the curriculum the Navy Program will provide a very high grade type of doctor to serve in the Navy and later in civil life. Great care has been taken to insure the selection of only those men best qualified to study medicine, regardless of their economic status, and to give these men the best possible medical education.

THE UNITED STATES PUBLIC HEALTH SERVICE AND THE WAR

Thomas Parran, M D

Surgeon General, U S Public Health Service

The wide range of activities in the U S Public Health Service calls for a diversification of medical talent seldom encountered in a single organization. At the present time more than 1,800 physicians are employed full time in the Public Health Service. Almost as many hold commissions in the inactive reserve or are serving part time or on a consultant basis.

The legal functions of the service cover the three broad divisions of medicine, namely research, clinical practice and public health practice. During the war these activities have been greatly expanded and new tasks have fallen to the lot of Public Health Service physicians. In fact, 90 per cent of our manpower, material and money have been channeled into direct war work. Virtually all of the research has been turned to new problems arising from the conditions of global war. Many confidential studies have been undertaken at the request of other branches of the government. Tropical medicine, industrial toxicology, aviation medicine and nutrition have captured the interest of our physicians in the research arm of the service. The production of vaccines, blood plasma and other biologic products has expanded greatly.

In our hospitals nearly 80 per cent of the patients are members of the Merchant Marine, the Coast Guard, the Army and the Navy. The Public Health Service furnishes medical care for the entire personnel of the Coast Guard in the same way in which the Navy Medical Corps provides medical care for the personnel of the Navy. Coast Guard patients treated in our hospitals have more than doubled in number since Pearl Harbor. Medical care is now extended by law to the families of coast guardsmen.

An increasing number of women and children are applying for admission to the marine hospitals, principally dependents of coast guardsmen. The addition of this valuable experience has made possible the development of clinical research in our hospitals, and with dramatic results. In 1942 a method for relieving the pain of childbirth was developed by Drs. Hingson and Edwards, two of our young officers at the Marine Hospital, Stapleton, N Y. Leaders in the medical profession consider this an outstanding contribution. Possibilities exist for the use of continuous caudal analgesia in surgical fields and are being explored. The originators of the method have demonstrated their technique at a number of medical schools.

In our cooperative program with the War Shipping Administration for medical care of trainees and members of the Merchant Marine we have expanded psychiatric work in the Public Health Service. Already an important field in our hospitals for the treatment of narcotic drug addicts, in the medical and psychiatric service of federal prisons and in St. Elizabeths Hospital, psychiatry is now being turned to the prevention and treatment of psychic effects of enemy attack on merchant seamen.

Public Health Service physicians are now on duty in practically every theater of war. Many are seeing actual combat as medical officers of the Coast Guard cutters. Others have been assigned to the Army in India and in the Southwest Pacific under the command of Generals Stilwell and MacArthur.

Another group of young physicians is doing a superb job under exceedingly arduous conditions. They are responsible for the medical care of 20,000 men who are constructing the Alaska Highway. Their patients are dispersed over a distance of 1,500 miles of virgin territory. As the highway has progressed northward they have had to move hospital supplies and equipment over great distances with inadequate transportation and in subarctic weather.

Other medical officers are serving with the United States Typhus Commission in Africa, with the Army in Panama in connection with venereal disease work and in Trinidad as members of the Anglo-American Commission.

Four of our doctors are in the first health expeditionary force to enter a foreign country after the reoccupation of Axis held territory. Assigned to the Office of Foreign Relief and Rehabilitation, they are in Africa and are working with local public health authorities and physicians to assure adequate medical supplies, allot food to combat widespread nutritional diseases among the native population and to improve native sanitation, malaria and typhus control for the protection of American troops in the area. The Office of Foreign Relief and Rehabilitation has requested the service to undertake the recruitment and training of the medical and sanitary personnel who will be needed as this important work expands to other war areas.

At the request of the Army a number of additional officers have attended the course in military government at the University of Virginia, and those who have completed the training are now on active duty.

For now and for the future, I would recommend to the medical student that he devote as much time and effort as possible to the study of public health methods and administrative medicine. In the past there has been scant attention to these subjects in our undergraduate schools. Yet their importance both in this country and in our international relationships is apparent. The day is rapidly passing when the training of public health physicians by the trial and error method of "experience" will suffice. Already postgraduate training in public health is being required of young physicians who have no compensating experience as a qualification for employment in state and local agencies.

The emergency made it necessary for the Public Health Service to recruit hundreds of physicians for assignment to public health positions in the states. To compensate, at least to some degree, for deficiencies in public health training, as well as to inculcate new employees in the policies and procedures of the Public Health Service, an orientation course was developed. Recruits were assigned to the course for the first six weeks of their employment. Lectures by experts in various fields, seminars, problem solving and field practice under supervision of a state health department were the methods utilized in the intensive training of physicians, many of whom were soon to be "on their own" in war communities which had never had a public health service before.

Within the total field of public health practice, two other specialties are expanding with amazing speed under the pressure of war. These are industrial hygiene and nutrition.

In 1942 the chairman of the Council on Industrial Health of the American Medical Association stated that teaching in this field is inadequate in most of our medical schools. He pointed out that, ironically enough, the Woman's Medical College of Pennsylvania devotes more time to the subject than any other school. Medical students and interns should certainly obtain a sufficient grounding in industrial medicine to recognize the possibilities in the field.

The United Nations Conference on Food and Agriculture held at Hot Springs, Va., May 18 to June 8, 1943, placed an important responsibility on public health and medicine in seeking the national and worldwide goal of better nutrition. The conference recognized that at all stages of a nutrition program, from the recognition of malnutrition in a community to its elimination, knowledge of the human body is essential. Because they possess and can contribute this knowledge, physicians have a primary responsibility in the development and application of a nutrition policy. The medical

student can look forward to making an even more significant contribution through the study of human nutrition. Modern nutrition—already one of the scientific miracles of our time—is a dynamic science on the threshold of fresh discoveries. It offers the student a rich field for exploration and practice.

In the past, war with all its destruction has been a catalyzer in the progress of medicine, surgery and public health. Already important changes are being reported in military medicine. On the public health front advances are being made. We are gaining new knowledge, devising new methods and new approaches. Our attacks on malaria, tuberculosis and venereal diseases have been sharpened by the development of new weapons. Today, in the protection of our armed forces and the civilian populations, and tomorrow, in the reconstruction to peace, the public health physician is an essential man whose knowledge and skill serve his country through constructive teamwork with the military surgeon and the private practitioner.

THE PROCUREMENT AND ASSIGNMENT SERVICE—CURRENT POLICIES

Harold S. Diehl, M.D.

Member, Directing Board

MINNEAPOLIS

The basic policy of the Procurement and Assignment Service relative to medical education remains unchanged from that enunciated in earlier issues of *THE JOURNAL*.¹ This is "to retain adequate teaching staffs for the medical schools, but to do so without withholding from military service more than a minimum number of men who are physically qualified for such service."

In the application of this policy, however, certain modifications of points of view and criteria of essentiality are inevitable as a result both of increases in the size and the activity of the armed forces and the depletions in teaching staffs combined with increased teaching loads in the medical schools.

The assumption of the offensive by our armed forces requires the services of far more young medical officers than are now available. At the same time critical shortages of medical services exist in certain war industries and civilian communities. These conditions demand that medical schools, hospitals and other agencies which utilize the services of physicians again review their staffs and release as many young physicians as possible for duty with the armed forces or to meet critical civilian needs.

Both the Army and the Navy report a dangerous shortage of young medical officers. In time of war the needs of these services must be given first priority. Unless the war is won the maintenance of civilian institutions will be futile and unless the boys who are fighting the war are supplied with adequate medical care lives will be unnecessarily lost and the prosecution of the war handicapped. This situation requires that medical schools and hospitals declare immediately available all physicians whose services are not absolutely essential and all who can be replaced by physicians who are ineligible for military service.

It is reported that some institutions have made little or no reduction in their staffs because many physicians ineligible for military service are available to them. This is obviously an unsatisfactory position when certain war industries and civilian communities and even other

hospitals are seriously short of physicians. Any institution which retains on its staff more physicians than are absolutely necessary is guilty of hoarding and is prejudicing the war effort and the national welfare.

On the other hand, medical schools have an equally great or even greater responsibility to maintain effective instructional programs for the students who are being trained as the physicians of the future. With the condensation of the medical course into three calendar years, with increases in the number of students and with depletions of teaching staffs, this is no easy assignment. Yet to fail to meet this responsibility would mean inadequately trained and incompetent physicians for both the armed forces and the civilian population. This would be a major tragedy. Medical schools are now engaged in war production and the product must not be defective. Incompetent medical officers are a hazard and liability just as are defective planes, tanks or guns.

INTERNSHIPS

The maintenance of twelve month internships with students graduating from medical schools at nine month intervals has resulted in an overlap of three months in the services of interns. Reports from many hospitals indicate that it is frequently an impossibility to utilize the services of interns effectively during this three month period. The result is unsatisfactory intern training and waste of medical manpower, neither of which can we afford at this time. Possibilities of adjustments in the internships are being studied by various groups with a view to the elimination of the unsatisfactory features of the present program.

RESIDENCIES

According to the policy of the Army, the Navy, Selective Service and the Procurement and Assignment Service, the determination of hospital residency is based only on the essentiality of the physician for the war effort. The question of the effect of the war on the medical schools is being studied.

The Procurement and Assignment Service is keenly aware of the necessity of providing essential medical services in hospitals and is doing everything within its power to accomplish this. On the other hand, residents are physicians in the age group most urgently needed by the Army and the Navy. As such those who are physically qualified have an obligation to go into service after a year of internship unless they are needed to fill essential hospital positions for which it is impossible to secure residents who are ineligible for military service.

Approximately six months ago hospitals were requested not to appoint as residents physicians who have failed to make bona fide applications for commissions. In order to provide for essential hospital services the Army and the Navy have granted a year's deferment of active military duty to certain residents who hold commissions and who have been recommended for deferment by the Procurement and Assignment Service. Some requests were denied because they were received too late and some because they did not seem to meet the conditions for deferment as set forth in the Procurement and Assignment Service memorandum on this subject.

Residents who do not hold commissions or who have not been officially rejected for commissions should be urged to apply for commissions at once and should not be appointed unless they do so. The Surgeon Generals

of the Army and Navy have assured the Procurement and Assignment Service that they will grant deferment of active duty until completion of the year of residency for residents who are granted commissions and whose applications for commissions are accompanied by Procurement and Assignment form 218, recommending that they be granted deferment as essential hospital residents.

There is evidence that some physically fit young physicians are avoiding military service by offering their services to hospitals as residents on condition that hospitals recommend deferment to Selective Service for them. If hospitals are parties to such practices, it may become impossible to secure deferment for residents who really should be deferred.

SUMMARY

The difficulties of maintaining effective medical schools and hospitals are becoming increasingly acute. To meet these problems it is essential that deans of medical schools, superintendents of hospitals and officials of the Procurement and Assignment Service be aware of the many urgent needs for physicians and assume a public spirited and statesmanlike attitude in passing on the availability or essentiality of individual members of medical school and hospital staffs. Only if this is done can the limited and dwindling supply of physicians be utilized effectively for the prosecution of the war and the safeguarding of the national welfare.

FORTY-THIRD ANNUAL PRESENTATION OF EDUCATIONAL DATA BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Victor Johnson, M D, Secretary

In this annual compilation of data on medical education, the Council includes the latest information available on the relationships of medical education to the war in the preceding statements from military and other government officials. The collaboration between the armed services, government agencies and institutions concerned with medical education must become even more intimate in the months ahead than it has been in the past. Successful solution of the complex problems of providing medical officers and civilian physicians in large numbers and in a relatively short period of time, consistent with a high quality of training, can come only through a continuation and expansion of the present excellent cooperation between the agencies involved.

This presentation also includes data on the military status of students, now undergoing a change, developments under the accelerated program, including the staggered admission and graduation dates, and an account of faculty participation in war activities. In addition there are data on enrolments, graduates, pre-medical education, licensure, internships, fees, continuation courses and specialty boards. Medical schools are described and recent educational developments discussed.

Reduced in volume through restrictions on the use of paper, the Educational Number of *THE JOURNAL* still provides essential material of great value to military and government agencies, the medical profession, medical educators, hospital officials, students, interns, residents and those concerned with specialty certification and graduate and postgraduate medical education. Reprints of the entire study as well as copies of the lists of hospitals are available and are widely distributed.

The Council and *THE JOURNAL* express thanks and appreciation to the military officials, the officers of the institutions mentioned and others for their cordial

cooperation in supplying the material submitted in this presentation and for other records furnished throughout the year to the office of the Council and the members of its staff on inspection or visitation, enabling the Council to maintain its medical student and hospital registers efficiently and to carry on its activities as outlined by the House of Delegates of the American Medical Association and to serve the profession.

SOLDIERS AND SAILORS IN MEDICAL SCHOOLS

In close cooperation with the Army and the Navy, the medical schools of America have zealously assumed a major wartime responsibility—the training of adequate replacements of medical officers for the armed forces. In June of this year nearly 15,000 medical students held army commissions in the Medical Administrative Corps and about 5,000 held ensign commissions in the Hospital Volunteers (Probation) of the Navy (see table 1 for distribution by schools). Only one school was without Army students and only three without Navy enrolments. This total number of nearly 20,000 medical students earmarked for military service represented nearly 87 per cent of the medical students in America, with approximately 65 per cent having Army affiliations and approximately 22 per cent having Navy affiliations.

The transfer of most of these students from the inactive commissioned status to the active status as privates and apprentice seamen is now being completed. In the active status they will be soldiers and sailors in school, not students in uniform. Data on the numbers actually in uniform are not yet available, since the processing of students is still progressing.

All Navy students are on commutation of ration and quarters. Of sixty-nine schools which have completed arrangements with the Army, in only nine are all

students housed in barracks and fed at common mess. Common housing and messing would seem to be educationally undesirable in most instances. Especially students in clinical work must of necessity follow an irregular program of meals and sleep. Such men are essentially student-physicians, responsible for sick

TABLE 1—Students Enrolled in Army or Navy Units on an Inactive Status in June 1943

Figures are incomplete in some instances because of pending applications for commissions. Many groups listed in this compilation have now been transferred to the active status and are in uniform as privates or apprentice seamen

patients whose hours of work are dictated by the unpredictable course of the illness of the patients assigned them. Although such considerations are less applicable to students in the basic sciences, it is true nonetheless that much of the value of an experiment may be lost

if a student is prevented from following an experiment to an inadvertently delayed conclusion by fixed times for meals. Taps at a regular hour may seriously interfere with study. It is gratifying that so small a proportion of medical students are subject to common housing and mess.

In conformity with orders from Army and Navy authorities, it seems apparent that drill and purely military instruction are sufficiently subordinated to the regular curriculum in most schools to present no interference with the chief responsibility of the medical school providing the prospective medical officer with the best in medical training. In only a few schools do such nonmedical activities involve as much as five or six hours a week, although in one school it totals ten hours a week.

THE ACCELERATED PROGRAM

Realizing the greatly expanding needs for medical officers and the continuing demand for civilian doctors—even anticipating such needs—many of the medical schools of the country increased their enrollments and adopted an accelerated curriculum even before Pearl Harbor. At present virtually all medical schools in the United States (including schools of basic medical sciences) are on the accelerated program, admitting a new class approximately every nine months and condensing the traditional four academic years of the medical curriculum into three calendar years by eliminating summer vacations, without a reduction in total classroom, laboratory or clinic hours. The only exceptions to this are the University of Michigan Medical School, which is on the full accelerated program but admits new freshman students once a year, the Woman's Medical College of Pennsylvania, which is on an accelerated program for the junior and senior years only and admits new first year students once a year, the University of Tennessee College of Medicine, which is on a full accelerated program and admits students approximately every three months, and the schools of basic medical sciences all of which are accelerating in that work which is offered and are admitting new students approximately every nine months.

Details of dates of admission and dates of graduation for the recognized four year schools are included in table 2. Admission dates for the schools of basic medical sciences follow in table 3. Of the latter schools two have developed four year programs. Bowman Gray now has junior and senior classes in operation and Utah has a junior class in session. It is noted that throughout the country new freshman classes will enter one or more medical schools during every month from September 1943 to January 1945 with the sole exception of the month of December 1944 (see table 4). Dates of graduation will also be staggered throughout these months. Table 4 includes estimates of numbers of graduates to January 1945. Most students will graduate in the months of December 1943 and September 1944, although some students will complete their work and be available for internships in every month of this period with the exception of the months of September 1943, May and November 1944 and January, 1945.

LICENSE UNDER THE ACCELERATED PROGRAM

All states in the Union as well as the District of Columbia, Alaska, Hawaii and Puerto Rico have adjusted their licensure legislation to present such adjustments were required. Under the accelerated medical program all the graduates

for admission to licensure, at least for the duration of the emergency. In Georgia no legislation has been introduced as yet. However, licensure difficulties in that state will not occur, according to a ruling of the Attorney General.

With the introduction of the Army and Navy premedical programs the question arises of licensure legis-

lation as it applies to the preliminary training of students admitted to medical schools. Present legislation in all states of the Union, the District of Columbia, Alaska, Hawaii and Puerto Rico makes it possible for students with two years of premedical training to become eligible for admission to licensure on completion of the medical curriculum. In general two academic premedical years have sufficed, even though this work may have been completed in less than two calendar years, by student attendance at summer sessions or by carrying more than the normal load of academic work per term or both. The Army Specialized Training Program for premedical studies calls for a total of fifteen calendar months of work, and the Navy V-12 program for premedical students provides for eighteen calendar months of training. In both of these programs the work is essentially continuous, without the long summer vacation, and provides for the student carrying more than the normal peacetime load of work per term. Both the Army and Navy programs provide for work well in excess of the sixty semester hours constituting the normal two academic years of premedical work required for licensure. Therefore it would seem that the Army and Navy premedical programs should offer no licensure difficulties.

It would also appear probable that requirements in specific premedical licensure fields such as chemistry, biology and physics will probably be adequately met by the Army and Navy programs.

In the past state licensing boards have accepted the statement of the dean of the medical school from which the applicant graduated which certified his premedical training. Presumably this practice will continue.

PREMEDICAL EDUCATION

The Army and Navy premedical programs fully satisfy the minimum requirements for admission to an approved medical school as these have been formulated

by the Council on Medical Education and Hospitals, as regards both total work and coverage of specific subjects. Heretofore most medical schools have required more than two academic years of premedical training for admission. In the academic year 1941-1942, only eight schools required but two years of premedical work, and in that year only 12 per cent of all freshmen entering medical schools in the United States had this minimum training.

However, all medical schools at the present time have decided that the completion of the Army or Navy premedical curriculum will fully meet their minimum admission requirements, in the cases of students in active service who have been assigned to the Army Specialized Training Program or V-12 premedical programs.

While recognizing the adequacy of the Army and Navy premedical programs for the admission of men in active military service, most schools desire also to publish admission requirements in terms of academic years or semester hours for civilian applicants. In tables 5 and 6 the present civilian premedical requirements are shown for each medical school in the United States and Canada. A degree is required by two schools, three years of work by twenty schools and a variable amount of work in excess of two years by five schools. The remaining fifty-nine schools require two preclinical years or less, even for civilian students applying for admission.

THE SUPPLY OF PHYSICIANS

The accelerated program and enrolment increases are now producing excellently trained medical graduates for military and civilian needs in numbers far exceeding the production of doctors at any time in the history of this country. In figure 1 is plotted the number of

medical graduates since 1905 including the estimated number of graduates in 1943 and 1944. The developments of far reaching importance in medical education in the United States all pertinent to the present war effort may be read from these data.

In 1905 the one hundred and sixty colleges in the United States produced 5000 graduates. There have been a large number of graduates parallel with the developments in the medical field.

ing from the closure of many proprietary schools and the enforcement of educational standards

Despite the reduced number of schools in recent years there has been a sustained increase in graduates, with a transient decrease in the years following 1939 resulting in part from the survey of medical schools conducted by the Council on Medical Education and Hospitals during 1934-1936

Before the results of the accelerated program were manifest in 1942 there were essentially as many graduates from seventy-seven approved schools maintaining high standards of medical training as there were thirty-five or forty years ago, when over twice the present number of medical schools operated, mainly without control over enrolments or standards

In the years 1943 and 1944 the number of graduates will far exceed the number at any time in the past history of this country. This wartime high may be contrasted with the all time low in medical graduates in

Figure 1 Numbers of medical schools and medical graduates in the United States, 1905-1942, and estimated for 1942-1945

1922, which also resulted from war—the low enrolment of freshman medical students in wartime 1918

Further data on the estimated future supply of physicians will be found under "Graduates" on p 1102

FACULTY MEMBERS IN WAR SERVICES

The accelerated program, increases in enrolment and decreases in resident personnel, have considerably increased the demands on medical school faculties. These demands are being met by faculties seriously depleted in numbers. On July 1, 1943 the seventy-six medical schools and schools of basic medical sciences in the United States had contributed a total of 5,637 of its faculty members to the armed forces.¹ This number is far in excess of the number of faculty members reported to be in active military service on July 1, 1942.² Although the figure 5,637 includes some men who are not physicians, it seems probable that more than 10 per cent of the medical officers in the armed forces (estimated at more than 47,000) have come from our faculties of medicine, which include in the neighborhood of 10 per cent of the physicians of the country. The interpretation and evaluation of these data are difficult, since many if not most of the teachers in active service were on a part time basis, in some instances contributing only an hour or two per week to instruction. Yet it

is apparent that medical schools seem to have contributed approximately as large a proportion of their faculty members to the armed forces as the proportion of physicians not engaged in academic work who have been commissioned

Further depletion of faculties has resulted from participation in war research. In twenty-one of the seventy-six medical schools there are 130 faculty members engaged in full time war research. This relatively small figure represents serious losses in teaching staff in some critical areas, since practically all these men were recruited from the full time faculty members mainly in the basic sciences. Furthermore, this figure includes only those on full time war research. The total loss in teaching manpower is much greater, since even larger numbers of teachers are devoting a considerable part, but not all, of their time to war research.

DEVELOPMENTS IN MEDICAL EDUCATION

The most noteworthy educational developments of the past year relate to the war and include the changes in premedical education, the transfer of students to an active military status, the adoption of the accelerated program by still more schools, and other wartime developments discussed in the earlier sections of this presentation.

Practically all schools report that, while the basic medical curriculum remains essentially unchanged, subjects of war significance are being stressed or have been added. The most commonly mentioned subjects in this category are Tropical Medicine and Parasitology, First Aid, Shock and Blood Substitutes, Burns and War Wounds, Venereal Diseases, Aviation Physiology and Medicine, Industrial Medicine and Public Health, Chemical Warfare, Military Medicine, Chemotherapy.

Two generalizations may be made from scanning this list. First, the subjects are not limited to clinical topics of a purely "practical" nature but involve as well material of basic scientific importance. Second, many of these subjects will continue to be of great medical importance after the war, so that these wartime additions to the curriculum are not simply necessary educational concessions to an emergency but will probably continue to justify their inclusion in our educational programs after the war.

Great impetus to the teaching of Tropical Medicine was given by grants from the John and Mary R Markle Foundation, administered by a committee of the Association of American Medical Colleges, for the training of teachers of Tropical Medicine at the Army Medical School in Washington and Tulane University. Intensive courses of two months each are given at each school. Men from many of the medical schools have taken these courses and are in charge of the teaching of Tropical Medicine in their own schools.

The Baylor University College of Medicine has moved its entire equipment, including laboratory desks, microscopes, instruments, museums and library, from Dallas to Houston. Preclinical laboratories and classrooms have been established in a spacious, well lighted building which will be utilized for these purposes during the war. Clinical work will be carried out at the Jefferson Davis (City-County) Hospital and the Hermann Hospital. Generous grants have been made to the school by the M. D. Anderson Foundation and the Houston Chamber of Commerce, to finance operations during the war and to construct buildings adjacent to Hermann Hospital to house the preclinical departments after the war. Dr. Walter H. Moursund comments

¹ Over 1,400 of these men are in the affiliated general hospital, evacuation hospital and surgical hospital units of forty-one medical schools. A list of these schools may be found in THE JOURNAL, Aug 15, 1942, p 1266, table 4.

² Three thousand and sixty faculty members from sixty-four schools were reported to be in active service at that time by Dr. Harold Diehl (J. A. Am. M. Coll. 18 15, 1943).

dean, and Dr. James A. Greene, formerly of Iowa, is professor and chairman of the department of medicine and dean of the clinical faculties, on a full time basis. His present major responsibility is the development of the program of clinical instruction.

Utilizing the former Baylor clinical facilities, including the Parkland Hospital, a new medical school has been organized in Dallas. Preclinical laboratories and class rooms are in operation or being established adjacent to Parkland Hospital in temporary quarters which will be used during the war. Funds raised by the Southwestern Medical Foundation and the Dallas Chamber of Commerce will support the new school in its temporary quarters during the war and in the construction of new buildings after the war. Most of the former Baylor faculty and many of its students remain in Dallas. The acting dean is Dr. Donald Slaughter, formerly of Baylor and more recently of Vermont.

A new medical school is also projected in Florida. On June 14 a bill became law in that state providing for the establishment of the University of South Florida, which is to be a state university having as its primary purpose the creation of a school of medicine, a school of pharmacy and a school of dentistry. The law further provides that the medical and dental schools shall be maintained and operated in accordance with the standards of education approved by the American Medical Association and the American Dental Association.

Despite the added demands made by the accelerated program and an expanding curriculum on faculties seriously reduced in numbers, developments of educational importance are projected by many schools, some of which involve basic principles of medical education in this country.

Increases in clinical facilities not only have strengthened weak spots at a number of schools but are fostering further extensions of the concept that effective clinical teaching must center about a physician-patient relationship between student and patient. Ward work and outpatient department assignments continue to increase. Purely didactic clinical instruction continues to decrease.

Several schools report the appointment of faculty committees to review the curriculum and make recommendations for closer collaboration between instruction in the various fields of medicine. In general, there are two definite tendencies.

First the line of demarcation between "preclinical" and "clinical" is becoming less sharply drawn. Medical instruction is being viewed as a four year unit rather than as two units of two years each. Introduction of well selected clinical material into the instructional program of the basic sciences is serving to emphasize the unity of the ends sought in medical education. Incorporation of material from the basic sciences into the work of the junior and senior years is stimulating a continued student interest in medicine as a science.

Second there is increased interdepartmental collaboration in the presentation of related material with the elimination of accidental needless repetition and provision for planned, desirable repetition. A given system or organ—for example the kidney—is being considered as a complex of problems the presentation of which requires the resources of collaborating biochemists, anatomists, physiologists, pathologists and renovascular clinicians rather than as a subject to be presented in turn by departments of biochemistry, anatomy, physiology, pathology and medicine.

A noteworthy development in the schools of basic medical sciences (see table 6) is the tendency toward expansion into schools offering the full four year curriculum. Bowman Gray is at present operating both senior and junior classes. It will graduate its first class in December 1943. Utah has started a junior class, which will graduate in August 1944. In Alabama a bill has been passed providing for the establishment of a four year medical school in that state, and appropriating \$1,000,000 for buildings and equipment and \$366,000 annually for maintenance. In at least two other states there has been discussion of expansion of the two year schools.

An arrangement has been consummated between West Virginia and the Medical College of Virginia whereby '15 to 20 students completing the work of the second year in the West Virginia School of Medicine in Morgantown will transfer to the Medical College of Virginia in Richmond for the completion of the four years curriculum, effective January 1944." This experiment in interschool collaboration may well yield results of value to other schools of basic medical sciences. It is becoming increasingly difficult to place students who have completed the basic sciences into schools with facilities adequate to accept transfer students and provide clinical instruction of high quality.

APPROVED MEDICAL SCHOOLS

Medical schools and schools of the basic medical sciences in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association for the academic session 1942-1943 are listed in tables 5 and 6, pages 1100, 1101 and 1102. The table includes quantitative premedical requirements for applicants not in the A S T P or V-12 premedical programs. The enrolment by classes, including fifth year students interning or engaged in research, the total attendance, which does not include fifth year students, and the number of graduates apply to the academic year immediately preceding the date of entrance of the first class entering in 1943. The data are treated in this way because of the irregularities in dates of commencement of the academic year and in dates of graduation, which have resulted from the adoption of the accelerated program. The name of the dean or acting dean is also given. Figures for the sixth year enrolment in Canadian schools are given in a footnote.

Four schools on a probationary status are indicated by asterisks. The University of Georgia School of Medicine has been reinstated on the list of approved schools, not on probation.

Three schools—Loyola, Wayne and Marquette, have discontinued the fifth year intern requirement for the M.D. degree. The numbers listed as graduating from these schools are high, since they include students who completed their four years of work in the last two academic sessions.

The fifth or intern year is now required for the M.D. degree by only six schools in the United States—College of Medical Evangelists, Southern California, Stanford, Northwestern, Minnesota and Duke.

The number of approved medical schools in the United States has been reduced to sixty-six since no classes have been in operation at the Rush Medical College since June 1942 when the last class graduated.

Historical information regarding all institutions on the approved list of medical schools maintained by the Council is given on pages 1111 to 1118.

ENROLMENTS

Enrolment figures by classes for the academic year ending with the admission of the first class in 1943 are given in tables 5 and 6 and recapitulated in table 7. In the seventy-six schools in the United States there were 22,631 students studying medicine (excluding the fifth year), which is an increase of 600 students, or 2.7 per cent above the preceding academic session. In the Canadian schools there were 2,386 students (excluding the fifth and sixth years), an enrolment increase of 48 students, or 2.0 per cent. In addition there were 566 fifth year students in schools of the United States plus 403 fifth year and 219 sixth year students in Canada.

STUDENTS BY CLASSES, 1931-1943

The number of students enrolled in preclinical and clinical classes and in internships when required for graduation in medical schools of the United States is shown in table 9, covering the past thirteen years. The numbers in each of the four classes in 1942-1943 show a substantial increase over the preceding academic session. The sophomore and junior classes were larger than at any other time for this period. The freshman class was larger than last year's on three occasions from 1930 to 1934. The senior class was larger in 1936-1937 than that of last year. The number entering as a requirement for the degree continued to fall because of schools dropping this requirement for the degree.

* On probation
These premedical requirements apply to civilian applicants in most instances. All schools in the United States will consider completion of the Army or Navy premedical program by male applicants on active duty as fulfilling academic admission requirements.
† Have started four year programs
‡ Completion of Army and Navy requirements
§ Third year students 33

In schools offering the complete four years of work the three schools in the United States with the highest enrolments were Illinois 661, Northwestern 581 and Jefferson 556. The three with the lowest enrolments were Woman's Medical College 119, Vermont 133 and Albany 155. In Canada the highest enrolment occurred at Toronto with 753 students in the six years, and the lowest at Alberta with 160 students in its five year course.

In no school of the basic medical sciences did the enrolment in either the freshman or the sophomore class exceed 50, with the sole exception of the freshman class at Alabama, which was 52.

The enrolment in the classes now in session in the United States is shown for each school in table 8. For comparison with enrolments in the two preceding sessions, total figures are also given in the last column of table 7. There are now 23,204 students in the schools in the United States. This is 573 students more than were in school in the academic session last completed, an increase of 2.5 per cent. The tendency toward increased enrolments each year continues. This serves the desired end of providing more medical officers and civilian physicians. However, each school should consider carefully whether available facilities warrant further increases and whether the quality of the educational product might not be inferior to that which is desirable not only in a medical officer but in civilian practice.

† The first four years in some Canadian schools do not correspond to those years in schools of the United States.
‡ Includes juniors at Utah and juniors and seniors at Bowman Gray.
§ Does not include 483 students in fifth and sixth years.

GRADUATES

In table 5 are included all graduates since July 1 1942 until the opening of the first academic session commencing in 1943. Such sessions opened in different schools anywhere from January to July. In the period thus defined there were 5,223 graduates. To this figure

may be added the estimated 10,889 students who will graduate is shown in table 4 between the time of the opening of the first academic session in 1943 and January 1945. The total figure, 16,112, is the number of students who have graduated or will graduate in a

period of thirty months from July 1 1942 to Jan 1 1945. For comparison with the figures on graduates of preceding classes, which have been expressed per calendar year, the figure 16,112 for thirty months may be converted into an average of 6,445 graduates per calendar year, which far exceeds the number ever graduated from schools in the United States even at the time when one hundred and sixty schools were operating in 1905.

This figure is a conservative expression of the probabilities, since there will probably be an additional 4,500

graduates in the first six months after Jan 1, 1945, totaling over 20,000 graduates in a period of exactly three years from July 1, 1942 to July 1, 1945, or nearly 7,000 a year. The latter figure is that estimated by Dr H G Wiskotten a year ago on the basis of far less information than is now available.

From table 5 it is seen that the three schools graduating the most students in the first academic session are Illinois 151 Harvard 148 and Jefferson 142. Marquette had 150 graduates, but these included students from two classes because of the elimination of the internship requirement for the M.D. degree. The smallest numbers were graduated from Vermont 31, Howard 27 and Woman's Medical College 22.

From the nine medical schools of Canada there were 496 graduates. The largest number 107, graduated from Toronto and the smallest number 30, received degrees from Western Ontario.

TABLE 9—Students in the United States by Years Including the Intern Year When Required for Graduation 1931-1943

Totals	24 183	1 317	5 448	271

Seven medical schools, including one in Canada, each enrolled more than 30 women, with 60 attending Toronto and 40 at New York University

There were 271 women graduates from sixty-three of the seventy-five four year schools In the United States there were 241 women graduates and 4,982 men Canadian schools graduated 30 women and 466 men

Table 17 shows the distribution of students and graduates by sex over a period of eight years Women students have not increased in numbers in the past year, so that the small increase in total enrolments, discussed earlier, is entirely due to an increase in the number of men in medical schools

The percentages of women enrolled and graduating in the United States since 1905 are shown in table 18

TABLE 17—Distribution by Sex in the United States and Canada, 1936-1943

Year	Students		Graduates	
	Male	Female	Male	Female
1935 1936	24 219	1,254	5 388	268

1941	1,146	5.4	260	5.3
1942	1 164	5.3	279	5.4
1943	1 180	5.1	241	4.6

For the academic year 1942-1943 the percentage of women enrolled was 5.1, a figure slightly lower than the percentages since 1937 The percentage of graduates who were women was 4.6, which is somewhat smaller than the percentages since 1938

Recent changes in Army regulations permit the commissioning of women physicians, although at present women students are not included in the Army or Navy medical or premedical programs Dr Margaret Craighill, dean of Woman's Medical College of Pennsylvania was the first woman physician to be commissioned in the United States Army Major Craighill is on leave of absence from the school

There is a women's division of the Procurement and Assignment Service, through which agency women are cooperating in the relocation of physicians In addition, women physicians are contributing greatly to the war

effort by carrying heavier loads than ever before, assuming the added responsibilities of men who have left for the armed forces

At the present time it is not anticipated that women will be included in the A S T or Navy A-12 Programs

LOAN FUNDS AND SCHOLARSHIPS

Under the accelerated program, the student with limited means faced the problem of financing his education without opportunities for earning money during summer vacations

Students were able to meet these needs largely because of the generous grants made by the W K Kellogg Foundation and loan funds made available by

the federal government Eighty-four schools in the United States and Canada received from the Foundation a total of \$977,700 in amounts ranging from \$5 000 granted to seven schools of basic medical sciences to \$16,000 These timely awards not only assisted deserving and needy medical students but constituted an important contribution to the war effort of the medical schools in carrying out the accelerated program

Of the \$5,000,000 appropriated by Congress for loans to students in various accelerated curriculums training for war participation, the largest single allotment was granted to students in medicine Through the United States Office of Education 3,628 loans were made to medical students in sixty-four medical schools and schools of basic medical sciences The total lent was \$1,063,573 75 for the fiscal year ended June 30, 1943

The Canadian government lent approximately \$150,000 to the students in six of the medical schools in that country

With the transfer of Army and Navy students to an active status in the United States, the need for

scholarship and loan aid is no longer acute A relatively small number of students (perhaps 15 to 20 per cent of the total) will be civilians Needy students in this group can probably be provided for by the local loan funds available in most schools In many instances

university and college funds set aside for loan purposes have increased in amount in the past year for several reasons. The Kellogg scholarship and loan funds for medical students and the government loan funds for students in several fields have resulted in a conservation of local funds. It should be emphasized that college loan funds would have been entirely inadequate to meet last year's emergency. In addition, large numbers of men in uniform in a variety of curriculums are having their expenses paid by the Army or Navy and need no loans. Finally, generally improved economic conditions have lessened the demand for loans.

There still remain funds for loans to students in the appropriation made by Congress for last year. Of the \$5,000,000 allocated for loans in several fields, about \$2,000,000 has not been lent. This sum is still available but may be used for loans only to those students who have previously received assistance through this appropriation. No new borrower is eligible for a loan from the fund this year.

PART TIME, SPECIAL AND GRADUATE STUDENTS

Students in these categories, shown in table 19 are included in none of the preceding tabulations. Part time and special students in the past year numbered about half as many as in 1941-1942. Under the acceler-

ated program and the programs for soldiers and sailors in school, part time students are now essentially limited to women and to men with no Army or Navy affiliation. Schools encouraging part time programs for superior students carrying research along with the work of the medical school regret this war casualty but recognize it as a necessity. In fourteen schools in the United States and Canada there were 70 such students in 1942-1943, as compared with last year's 132.

Special students include those carrying work in such fields as public health, physicians reviewing for specialty board examinations, and students preparing to become physical therapists or laboratory technicians. Curriculums in these and other fields may involve some work in the medical school. There were 190 such special students reported from twenty-six medical schools as compared with 416 in 1941-1942. Forty-two took work at Northwestern, 34 at Tennessee and 29 at Texas. Other schools reported 12 or less.

There were 434 students not candidates for the medical degree pursuing medical subjects in seventeen medical schools in the United States and Canada. A number of these are students enrolled in the graduate school of the University. Over 70 such students were enrolled in each of four schools. Illinois, Northwestern, New York University and Meharry.

GRADUATES WITH BACCALAUREATE DEGREES

At the present time no school in the United States requires a degree for admission, although four schools (Kansas, Dartmouth, Western Reserve and Vander-

bilt) in 1942-1943 required the student to earn a degree during the first year in medical school. Two Canadian schools (Montreal and Laval) required the degree for admission. Yet 76 per cent of all graduates from the seventy-five four year schools in the United States and Canada also held baccalaureate degrees, as shown in table 20. This does not include those earning the B.S. in Medicine, which are presented in the next section.

In the United States 4,099 of the 5,223 medical graduates also held baccalaureate degrees, and in Canada 253 of the 496 medical graduates also held the additional degree. The percentage of graduates in Canada holding both degrees was approximately half that of the graduates of medical schools in the United States. All the graduates of the following seven schools held both degrees: Yale, Albany, Cornell, Western Reserve, Oregon, Jefferson and Laval. Three schools having a degree requirement graduated 10 students with less than their stated college education. None of the graduates of Alberta held the baccalaureate degree.

GRADUATES WITH THE B.S. IN MEDICINE

Certain graduates of twenty-seven medical schools in the United States and 1 in Canada received the Bachelor of Science degree in Medicine. There were 416 such degrees awarded in the United States and 2 in Canada, a total of 418. The largest single group to receive the degree were 87 graduates of Illinois. Minnesota awarded 74 degrees and Indiana 46. Other schools granted 34 or less and eighteen schools granted less than 10 each.

FEES

The eighty-six medical schools and schools of basic medical sciences in the United States and Canada have been arranged in six groups in table 21 according to the tuition fees charged resident students for the session of 1942-1943. The data are based on the average tuition fee charged for the complete medical course and includes minor charges as for matriculation, breakage, diploma and graduation.

Three medical schools, Oklahoma, Texas and West Virginia, charged less than \$99 for the year. Twenty-six schools, most of which are in the Eastern section of the country, had fees of \$500 or more. College of Medical Evangelists, Yale, George Washington, Georgetown, Loyola, Tulane, Johns Hopkins, Maryland, Tufts, Mississippi, St. Louis, Washington, Albany, Columbia, Cornell, Long Island, New York Medical, New York University, Syracuse, Buffalo, Rochester, Cincinnati, Western Reserve, Hahnemann, Pennsylvania and Pittsburgh. Mississippi is the only addition to this group in the last year. The total number in the group has not changed, since Rush is no longer in the list.

The trend toward increases in tuition continues. The average resident fees charged by medical schools in the United States in the past four years, ending with the year 1942-1943, have been \$378, \$386, \$395 and \$407.

Thirty-one schools in the United States and six in Canada make an additional charge for non-residents. These sums vary considerably in amount. Toronto charges \$5 for first year students and \$10 for others. Four schools charge \$50 or less annually. Louisiana and Michigan charge \$400 annually. South Carolina charges \$420.50 for each of its two years, and Texas a \$600 fee for each of the third and fourth years.

DESCRIPTION OF MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 30 professors and 112 lecturers and instructors, a total of 142. The curriculum covers four sessions of nine months each. Entrance requirements are two years of collegiate work. The B.S. Degree is conferred at the end of the second year. An accelerated program was adopted July 1, 1943, involving the admittance and graduation of a class approximately every nine months. The fees for the four years for residents of Arkansas are \$280 per year; nonresidents are charged \$225 additional each year. The registration for 1942-1943 was 284 graduates 70. The present session began July 1, 1943, and ends March 27, 1944. The Dean is Byron L. Robinson, M.D.

CALIFORNIA

Berkeley-San Francisco

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL University Campus Berkeley Medical Center, San Francisco—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909 by legislative enactment the College of Medicine of the University of Southern California at Los Angeles became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged and elective chairs in homeopathic materia medica and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. For the emergency students may be accepted who have completed premedical work in two years or six terms. The work of the first year is given at Berkeley and that of the last three years at San Francisco. An accelerated program has been adopted consisting of three terms of sixteen weeks in each academic year. The medical course may now be completed in two and two-thirds years. The faculty is composed of 171 professors and 306 associates and assistants, a total of 477. The fees average \$318 per academic year; nonresidents are charged \$250 additional each year. The registration for 1942-1943 was 260 graduates 53. The present session began February 11, 1943, and will end October 23, 1943. The subsequent session begins October 28, 1943. The Dean is Francis S. Smyth, M.D., San Francisco.

Loma Linda-Los Angeles

COLLEGE OF MEDICAL EVANGELISTS Loma Linda Boyle and Michigan Avenues Los Angeles—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. Coeducational since organization. Three years of collegiate work are required for admission. The faculty is composed of 45 professors and 350 associate professors, assistant professors, instructors and assistants—making a total of 395. The course covers a period of three years of four nine-month academic sessions and an additional twelve-month internship in an approved hospital. The total fees are, respectively \$602 \$590 \$612 and \$617. The registration for 1942-1943 was 319 graduates 82. The present session for the sophomore, junior and senior sessions began April 4, 1943, and will end December 1944; the freshman session will begin July 1, 1943, and will end March 1944. The subsequent junior and senior sessions begin January 1944; freshmen and sophomore sessions begin April 1944. The President is Walter E. Macpherson, M.D., Los Angeles. The Dean is Newton Evans, M.D., Loma Linda. The Assistant Dean is W. F. Norwood, Ph.D., Los Angeles.

Los Angeles

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE 3551 University Avenue—Organized in 1895 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Los Angeles Medical Department of the University of California. In 1939 the College of Physicians and Surgeons established in 1904 became the Medical Department of the University of Southern California. Its activities were suspended in 1920, reorganized in May 1928 under present title. During present national emergency will operate the year round on accelerated three term basis each term continuing for sixteen weeks. The 1943 entering class began instruction on June 28, 1943. Subsequent entering classes will begin at 8 month intervals during the emergency. The faculty consists of 156 professors and 239 instructors, assistants, and others—a total of 395, 129 of whom are now on active duty with the armed forces. An internship is required for graduation. Coeducational since organization. Annual fees (1½ academic years) amount to \$842. The registration for 1942-1943 was 218 graduates 45. The present session began June 28, 1943, and will end January 15, 1944. The Dean is Burrell O. Raulston, M.D.

Stanford University-San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE University Campus Stanford University 2598 Sacramento Street San Francisco The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry and physiology are located on the campus at Stanford University which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is

Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 138 professors and 190 lecturers, assistants and others a total of 328. Three years of collegiate work are required for admission. The quarter plan is in operation admitting one class each year. An internship is a requirement for graduation. The fees for the four years respectively are \$474 \$438 \$418 and \$418. The registration for 1942-1943 was 239 graduates 62. During 1943-1944 the quarters begin June 28, October 11, January 10, April 12, July 10. The Dean is Loren Roseoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE 4200 East Ninth Avenue—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants a total of 187. The accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The entrance requirements for nonmilitary students are three years of collegiate work. The fees average \$289 per academic year; nonresidents are charged \$245 additional each year. The registration for 1942-1943 was 222 graduates 49. The present session began March 29, 1943, and will end December 1943. The subsequent session will begin January 3, 1944. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE 333 Cedar Street—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812 instruction began in 1813. First class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884 the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887 Yale College became Yale University. Coeducational since 1916. The faculty consists of 199 professors and 187 lecturers and assistants a total of 386. Of this number 23 are on leave of absence for war service and about 75 other staff members are in the armed forces. The requirements for admission are two years of collegiate work. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The fees average \$506 per academic year. The registration for 1942-1943 was 214 graduates 44. The present session began April 5, 1943, and will end December 18, 1943. The subsequent session will begin December 27, 1943. The Dean is Francis G. Blake, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE 3900 Reservoir Road N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 61 professors, 42 associate professors, 13 assistant professors, 18 adjunct professors and 146 instructors a total of 280, of whom 65 are on military leave. Minimum requirements for admission are the complete premedical Army Specialized Training Program or Navy College Training Program. Civilian students must finish at least two full years of premedical work in an approved college of arts and sciences. The accelerated program permits admission and graduation of a class every nine months. The fees average \$520 per academic year. The registration for 1942-1943 was 297 graduates 69. The present session began March 15, 1943, and will end December 15, 1943. The subsequent session begins January 3, 1944. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE 1335 H Street N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838 and 1861 to 1863 inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1903 it absorbed the National University Medical Department. In 1904 by an Act of Congress the title of George Washington University was granted to the institution. Coeducational since 1884. The faculty is composed of 81 professors and 150 instructors, demonstrators and assistants a total of 231. Sixty semester hours of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The fees average \$500 per academic year. The registration for 1942-1943 was 281 graduates 71. The present session began March 1, 1943, and will end November 6, 1943. The subsequent session will begin November 22, 1943. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE Fifth and W Streets N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 41 professors and 61 instructors and assistants a total of 102. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. The fees are respectively \$269 \$269 \$269 and \$269. Registration for 1942-1943 was 226 graduates 27. The curriculum was accelerated with the beginning class of September 1942. Classes will be admitted every 9 months as follows: June 1943, March 1944, January 1945. The 1943-1944 session began June 12, 1943, and ends March 18, 1944. The Dean is John Wesley Lawless, M.D.

GEORGIA

Atlanta

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915, assumed present title in 1917. Two years of collegiate work are required for admission. The course of study is four academic years of thirty-two weeks each. By the use of the long summer vacation as a teaching quarter, the time required for the completion of these four academic years has been reduced from four to three calendar years. This is in line with the accelerated program adopted by most medical schools during the present emergency. The fees for each of the four academic years are \$357. The registration for 1942-1943 was 226, graduates, 52. Classes this year began on March 23, 1943 and will end December 23, 1943. The subsequent session will begin January 3, 1944 (tentative). The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 62 professors and 24 assistants, a total of 86. Three years of collegiate work are required for admission (except that for the duration of the present war the minimum requirement will be two years). An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$225 per academic year for residents of Georgia; nonresidents are not admitted. The registration for 1942-1943 was 242, graduates, 46. The present session began April 7, 1943, and will end December 20, 1943. The subsequent session will begin January 3, 1944. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue—Organized in 1915 by acquisition of Bennett Medical College, which had been organized in 1869. Facilities enlarged upon by acquisition of Chicago College of Medicine and Surgery, faculties in basic medical sciences put on full time basis and present title assumed in 1917. Operated as an organic part of Loyola University. Coeducational since organization. The faculty is composed of 38 full time professors and 288 associate and assistant professors, associates, instructors and assistants, a total of 326. Ninety semester hours of collegiate work are required for admission. The fees average \$515 per academic year. The registration for 1942-1943 was 290, graduates, 114. The present session for all classes began on April 19, 1943 and will end December 31, 1943. The subsequent session will begin January 3, 1944. The Dean is Francis J. Braceland, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises 31 professors, 139 associate and assistant professors and 493 associates, instructors and clinical assistants, a total of 663. For the duration of the war the requirement for admission is two years of collegiate work. The B.S. in medicine degree may be conferred before the end of the sophomore year. An accelerated program has been adopted involving the acceptance of a class every nine months. A hospital internship is required for graduation. The total fees are \$414 each year. The registration for 1942-1943 was 581, graduates, 138. The present session began March 29, 1943 and will end December 18, 1943. The subsequent session will begin December 28, 1943. The Dean is J. Roscoe Miller, M.D.

UNIVERSITY OF CHICAGO, THE SCHOOL OF MEDICINE, Fifty Eighth Street and Ellis Avenue—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932 when the University of Chicago reorganized its departments, the medical departments were included in the Biological Sciences Division. The work of the first two years in the medical courses has been given on the University Quadrangles since 1899 but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. The faculty of the School of Medicine is composed of 90 professors, 125 associates, instructors and others, a total of 215. The requirements for admission are 80 semester hours of collegiate work or completion of the Army or Navy premedical program, whether or not the applicant is actually in the Army or Navy. The B.S. degree may be obtained during the second year. The curriculum covers twelve quarters of work.

Sixty-five students are admitted to the first year class every nine months. The tuition fee averages \$450. The registration for 1942-1943 was 251 graduates, 42. During the academic year 1943-1944 the quarters will begin June 22, September 28, January 3 and March 27. Classes will be admitted only in January and September 1944. All correspondence relating to general policies should be addressed to W. H. Tahaferro, Ph.D., Dean of the Division of Biological Sciences, or to A. C. Bachmeyer, M.D., Associate Dean, and that pertaining to student affairs to B. C. H. Harvey, M.D., Dean of Medical Students.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1853 West Polk Street—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relationship with the university was cancelled in June 1912, and was restored in March 1913, when the present title was assumed. Coeducational since 1898. Two years of collegiate work are required for admission. The accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The B.S. in medicine degree is conferred at the end of the second year. The faculty is composed of 165 professors and 394 associates, instructors and assistants, a total of 559. The fees for residents of Illinois average \$288 per academic year; nonresidents pay an additional fee of \$150. The registration for 1942-1943 was 661, graduates, 151. The present session for juniors and seniors began March 29, 1943 and will end December 17, 1943. Freshmen and sophomores enrolled June 28, 1943 and will complete the year March 25, 1944. The Dean is David J. Davis, M.D., until September 1, 1943, Raymond B. Allen, M.D., after September 1, 1943.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE, Bloomington, 1040 West Michigan Street, Indianapolis—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 334 professors, lecturers, associates and assistants. The B.S. degree in medicine is conferred. The school has been on an all time program since May 11, 1942. Each calendar year is divided into three terms. The work given in two terms is equivalent to the work formerly given in a year. The work of the first two terms is given at Bloomington, the remainder of the work at Indianapolis. Regular fee for two terms of work is \$217 for residents of Indiana and \$422 for nonresidents. The registration for the session 1942 was 486, graduates, 104. The next regular class will start work on September 6, 1943. The Dean is Willis D. Gatch, M.D., Indianapolis.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 professors, 74 lecturers, demonstrators and assistants, a total of 130. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The tuition fee is \$226 each year for residents of Iowa and \$490 for nonresidents. The registration for 1942-1943 was 311, graduates, 63. The present session began March 1, 1943 and will end December 18, 1943. The subsequent session begins January 3, 1944. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE, Lawrence, 39th Street and Rainbow Boulevard, Kansas City—Organized in 1880. It offered only the first two years of the medical course until 1905 when it merged with the Kansas City (Mo.) Medical College, founded in 1869 and the College of Physicians and Surgeons founded in 1894 and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. The first class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 78 professors and 136 instructors, assistants and others, a total of 214. The requirement for admission is three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees for residents of the state average \$229.30; nonresidents \$432.11. The registration for 1942-1943 was 300, graduates 92. The first session for freshmen began May 24, 1943. Upper classmen were enrolled May 19, 1943 and will complete the year January 27, 1944. The Dean is H. R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838 and a class graduated each year except 1863. In 1846 the name was changed to University of Louisville.

ville Medical Department In 1907 it absorbed the Kentucky University Medical Department in 1908 the Louisville Medical College the Hospital College of Medicine and the Kentucky School of Medicine In 1922 it changed its name to the University of Louisville School of Medicine Coeducational since organization Two years of collegiate work are the minimum requirement for admission Preference is given applicants with a degree or three college years leading to a degree The faculty numbers 72 professors and 70 assistant instructors and others a total of 148 An accelerated program has been adopted involving the admittance and graduation of a class every nine months Fees average \$452 per academic year The registration for 1942-1943 was 365, graduates 92 The present session began April 1 1943 and will end December 4 1943 The subsequent session will begin January 5 1944 The Dean is John Walker Moore MD

LOUISIANA

New Orleans

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE 1542 Tulane Avenue.—Organized January 1931 as Louisiana State University Medical Center Present title in 1939 Coeducational First session October 1931 with students of first and third year Faculty comprises 25 professors and 103 associate professors assistant professors instructors and assistants a total of 128 Course covers four sessions of not less than 32 weeks each Under the accelerated program adopted for the duration of the war a first year class will be admitted each nine months and the entire course will be completed within a period of three years A minimum of two years collegiate work is required for admission Total fees \$134 each year for residents of Louisiana additional tuition of \$400 each year for nonresidents The registration for 1942-1943 was 344 graduates 78 The present session began March 11 1943 and will end December 15 1943 The Dean is B I Burns MD

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE 1430 Tulane Avenue.—Organized in 1854 as the Medical College of Louisiana Classes were graduated in 1835 and in all subsequent years except 1863 1865 inclusive It became the Medical Department of the Tulane University of Louisiana in 1884 Present title in 1913 Coeducational since 1915 The faculty comprises 31 professors and 220 associate and assistant professors instructors and assistants a total of 251 An accelerated program has been adopted involving the admittance of a class at the beginning of each ninth month and the graduation of a class approximately every eight months A minimum of two years of collegiate work is required for admission Total fees average \$547 per academic year The registration for 1942-1943 was 310 graduates 121 The present session began July 1 1943 and will end February 12 1944 The Dean is Hiram W Kostmayer MD

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE 710 North Washington Street.—The nucleus of a Medical Faculty was constituted in 1883 Systematic postgraduate instruction in pathology and bacteriology was begun in 1886 School was fully organized and opened in 1893 The first class graduated in 1897 Coeducational since organization The faculty consists of 70 professors and 397 instructors assistants and others a total of 467 The requirement for admission is temporarily two college years An accelerated program has been adopted involving the admittance and graduation of a class every nine months The fees average \$627 per academic year The registration for 1942-1943 was 288 graduates 73 The present session began March 1 1943 and will end November 25 1943 The subsequent class will begin November 29 1943 The Dean is Alan M Chesney MD

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland The first class graduated in 1810 In 1812 it became the University of Maryland School of Medicine Baltimore Medical College was merged with it in 1913 In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed Coeducational since 1918 The faculty consists of 52 professors and 332 associate and assistant professors and others a total of 384 of which 137 are now absent serving with the Armed Forces Premedical college training reduced from three to two years for the duration of the war The medical school is now running under an accelerated program for the duration of the war and requires the admission of a freshman class approximately every nine months The tuition fees average \$501 for residents of the state for nonresidents approximately \$150 additional The registration for 1942-1943 session was 373 graduates 98 Present session began April 8 1943 and will end December 23 1943 The next subsequent session will begin January 13 1944 The Dean is Robert U Patterson MD

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE 80 East Concord Street.—Organized in 1873 as a homeopathic institution In 1874 the New England Female Medical College founded in 1848 was merged into it The first class was graduated in 1874 Became nonsectarian in 1918 Coeducational since organization Two years of collegiate work are required for admission The faculty includes 22 professors 207 associates and others a total of 229 An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months Total fees average \$480 per year The registration for 1942-1943 was 225 graduates 44 The present session began March 31 1943 and will end December 7 1943 for first year students December 14 1943 second and third year students and December 11 1943 for fourth year students The subsequent session begins December 31 1943 The Dean is Bennett F Avery MD

In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. The faculty comprises 142 professors and 303 lecturers, instructors and others, a total of 445. For the duration of the war the entrance requirement has been reduced to two years of collegiate work. The B. S. degree in medicine is conferred at the end of the third or fourth year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$526. The registration for 1942-1943 was 374, graduates, 94. The present session began March 29, 1943 and will end December 18, 1943. The subsequent session begins January 3, 1944. The Dean is Philip A. Shaffer, Ph. D.

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 79 professors and 76 instructors, lecturers and assistants, a total of 155. Sixty-four semester hours of collegiate work are required for admission. The B. S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$376 per academic year and \$100 additional each year for students who have not taken the major part of their work at Creighton University. The registration for 1942-1943 was 241, graduates, 44. The present session began March 18, 1943 and will end December 20, 1943. The subsequent session will begin January 4, 1944. The Dean is Charles M. Wilhelm, M. D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty Second Street and Dewey Avenue—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 78 professors and 54 lecturers and instructors, a total of 132. Two years of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The B. S. degree in medicine is conferred at the end of the second year. The fees average \$250 per academic year. The registration for 1942-1943 was 332, graduates, 74. The present session began March 26, 1943 and will end December 18, 1943. The subsequent session will begin January 3, 1944. The Dean is C. W. M. Poynter, M. D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The faculty is composed of 93 professors and 118 instructors, assistants and others, a total of 211. For the duration students who have completed two years of college and who have the proper specific qualifications will be admitted. This change in the requirements for admission has been instituted for the duration of the present national emergency. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$532 per academic year. The registration for 1942-1943 was 155, graduates, 34. The present session began March 29, 1943 and will end December 24, 1943. The subsequent session will begin January 3, 1944. The Dean is R. S. Cunningham, M. D.

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street—Chartered in 1930, was originally organized in 1858 as The Long Island College Hospital. From the collegiate department the first class was graduated in 1860 and the last class in 1930. The first class of the Long Island College of Medicine was graduated in 1931. It is coeducational. It has a faculty of 131 professors, associate assistant, clinical and assistant clinical professors, and 196 lecturers, associates, instructors, assistants, and others, a total of 327. For the duration of the war two years of collegiate work, including specified courses, are required for admission. The medical course covers four academic years but is being given in three calendar years for the duration of the war. The fees average \$610 per academic year. The registration for 1942-1943 was 399, graduates,

88. The present session began March 29, 1943 and will end December 23, 1943. The subsequent session begins January 3, 1944. The President and Dean is Jean Alonzo Curran, M. D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 99 professors and 177 associates, assistants and others, a total of 276. The minimum requirement for admission is two years of collegiate work including certain prescribed science subjects. An accelerated program has been adopted admitting a freshman class every nine months. The fees for the entire course are \$2,000. The registration for 1942-1943 was 276, graduates, 66. The present session for freshmen began July 6, 1943 and ends March 25, 1944. The subsequent session for freshmen begins April 3, 1944. The Dean is Edward W. Koch, M. D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty Eighth Street—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807. In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 290 professors and 614 instructors, demonstrators and others, a total of 904. Two years of collegiate work are required for admission. During the war, the school will remain in session throughout the year and entering classes will be enrolled at intervals of approximately nine months. Fees average \$538 per academic year. The registration for 1942-1943 was 448, graduates, 95. The present session began March 22, 1943 and will end December 23, 1943. The subsequent session begins January 1, 1944. The Dean is Willard C. Rappleye, M. D.

NEW YORK MEDICAL COLLEGE, FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869. The title New York Homeopathic Medical College and Hospital in 1881, the title New York Homeopathic Medical College and Flower Hospital in 1908, the title New York Medical College and Flower Hospital in 1936. The present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. Two years of college work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. It has a faculty of 67 professors and associate professors, 48 assistant professors, 291 lecturers and assistants, a total of 406. The fees average \$663 per academic year. The registration for 1942-1943 was 340, graduates 68. The present session began March 29, 1943 and will end Dec 20, 1943. The subsequent session begins January 3, 1944. The President and Dean is J. A. W. Hetrick, M. D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841. In 1898 it united with the Bellevue Hospital Medical College, organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. Coeducational since 1919. The faculty is composed of 203 professors, associate, assistant, clinical and assistant clinical professors and 348 lecturers, instructors and others, a total of 551. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Entrance requirements are two full years of study in an approved college of arts and sciences. The fees average \$600 per academic session. The registration for 1942-1943 was 505, graduates, 124. The present session began April 5, 1943 and will end in December 1943. The subsequent session begins January 3, 1944. The Acting Dean is Donald Sheehan, M. D.

CORNELL UNIVERSITY MEDICAL COLLEGE 1300 York Avenue—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. The faculty is composed of 171 professors and 351 instructors, assistants and others, a total of 525. All students admitted are from approved colleges for premedical training. In the past students accepted have been holders of a college degree or candidates for the degree on successful completion of the first year of medicine. A thorough premedical training is still regarded as a desirable attainment but for the duration of the present emergency students may be accepted who have completed only two years of college. An accelerated program has been adopted whereby a class graduates and a new class enters every nine months. The fees average \$622 per academic year. The registration for 1942-1943 was 314, graduates 75. The present session began April 5, 1943. The subsequent session will begin January 3, 1944. The Dean is Joseph C. Hinsey, Ph. D.

Rochester

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE AND DENTISTRY, 260 Crittenden Boulevard—Organized in 1923 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 74 professors, 207 lecturers, assistants, instructors and others, a total of 281. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Three years of collegiate work are required for admission.

sion. The fees average \$500 per academic year. The registration for 1942-1943 was 245 graduates 50. The present session began March 29 1943 and will end December 18 1943. The subsequent session begins January 3 1944. The Dean is George Hoyt Whipple M.D.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE 766 Irving Avenue—Organized in 1872 when the Geneva Medical College chartered in 1834 was removed to Syracuse under the title The College of Physicians and Surgeons of Syracuse University. Present title assumed in 1875 when a compulsory three-year graded course was established. The first class graduated in 1875 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 64 professors and 192 associate and assistant professors lecturers and instructors a total of 256. Two years of a recognized college course are required for admission. An accelerated program has been adopted involving the completion of the four-year course in three years admitting a freshman class every nine months. The fees average \$600 per academic year. The enrollment for 1942-1943 was 184 graduates 41. The present session for upper classmen began April 5 1943 and will end December 1943 and for freshmen July 1943. The subsequent session will begin in April 1944. The Dean is H. G. Weiskotten M.D.

NORTH CAROLINA

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE—Organized in 1925. The first class was admitted October 1 1930. Coeducational. The faculty is composed of 11 professors and 213 associate and assistant professors lecturers instructors and assistants a total of 224. The premedical requirement is two years of college work. The academic year consists of four quarters of eleven weeks each which must be taken consecutively with graduation in three calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. Active duty with the Army Navy or Public Health Service can replace the second year. The fees are \$450 for each year of three quarters. The registration for 1942-1943 was 264 graduates 61. During 1943-1944 the quarters begin July 1 September 27 January 3 March 31 and end September 22 December 20 March 26 and June 22. The first year students will be enrolled January 3 1944 and September 29 1944. The Dean is Wilhert C. Davison M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICINE Eden and Bethesda Avenues—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement March 2 1909 the Miami Medical College also merged with the University when the title of Ohio-Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class will be accepted in accordance with the Army and Navy plan for the training of medical students for the duration of the war. Liberal Arts students of the University of Cincinnati may sign up for the seven-year combined Liberal Arts and Medical program. The B.S. degree is granted on the joint recommendation of the faculties of the College of Liberal Arts and Medicine at the end of the first medical year. The faculty consists of 112 professors associate and assistant professors 350 instructors etc. a total of 462. During the period of the war emergency the college will operate on an accelerated program. A new class will be admitted every nine months. Each session will consist of thirty-six weeks of work and there will be a short recess between the major sessions. The present session began March 22 1943 and will end December 1943. The subsequent class will be admitted December 1943. Tuition is as follows: For legal residents of Cincinnati \$485 a year plus breakage fees (\$50 additional for those not legal residents). The registration for 1942-1943 was 308 graduates 76. The Dean is Stanley Dorst M.D.

Cleveland

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE 2109 Adelbert Road—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844 (a celebration of the Centenary is planned for October 27 1943). The school assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 101 professors and 276 lecturers assistants and others a total of 377. The curriculum covers four scholastic years of 38 weeks each including four weeks of intermission. During the war emergency these will be continuous so that the entire course will be completed in 150 weeks. For the duration of the war the entrance requirements have been reduced to two years of college work. The fees average \$329 per academic year. The registration for 1942-1943 was 306 graduates 69. The present session began March 1 1943 and will end October 28 1943. The subsequent session begins November 22 1943. The Dean is Torald Sollmann M.D.

Columbus

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE Neil and Eleventh Avenues—Organized in 1907 as the Starling Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willoughby Medical College which was chartered March 3 1834) with the Ohio

Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 93 professors associate and assistant professors 119 lecturers instructors demonstrators and others a total of 212 of whom 70 are on military leave. Two years of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. For first and second year students the next session will begin September 1, 1943, and end May 20, 1944. The Dean is Margaret D. Craighill, M.D., who is on leave of absence for military service. The Acting Dean is Marion Fay, Ph.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard—Organized in 1886, as the Western Pennsylvania Medical College and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 30 professors and 370 associates, assistants and others, a total of 400. Entrance requirements are two years of collegiate work. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The total fees are \$500 each year. The registration for 1942-1943 was 336, graduates, 72. The present session began April 5, 1943 and will end about December 18, 1943. The subsequent session will begin January 3, 1944. The Dean is W. S. McElroy, M.D.

SOUTH CAROLINA

Charleston

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lucas Street—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college hearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn, being restored in 1917. It has a faculty of 43 professors and 73 associates, instructors and others, a total of 116. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Two years of collegiate work are required for admission. The total fees are \$272 each year. Fees for nonresidents of the state, \$422 each year. The registration for 1942-1943 was 189, graduates, 48. The present session began March 29, 1943 and will end December 22, 1943. The subsequent class will begin January 3, 1944. The Dean is Robert Wilson, M.D.

TENNESSEE

Memphis

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue—Organized in 1876 at Nashville as Nashville Medical College. First class graduated in 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 139 professors and 157 assistants, instructors and others, a total of 296. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1942-1943 was 510, graduates, 109. During the academic year of 1943-1944 the quarters

begin July 5, September 23, January 3 and March 23, and end September 22, December 11, March 18 and June 7. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue North and Heffernan Street (For Negro Youth)—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 49 professors and 30 instructors and lecturers, a total of 79. Two years' work in a college of liberal arts are required for admission. Tuition fees are, respectively, \$325, \$315, \$305 and \$315 each year. The curriculum covers four academic years of thirty four weeks each. Registration for 1942-1943 was 242, graduates, 50. The next session begins March 1944. In September 1942, Meharry Medical College instituted the quarter system. Meharry initiated an accelerated schedule in July 1943. The Dean is Michael J. Bent, M.D., the President is Edward L. Turner, M.D.

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty First Avenue South at Edgehill—This school was founded in 1874. The first class graduated in 1875. Coeducational since 1925. The faculty numbers 255. For matriculation, civilian students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully one year of work in the school of medicine. Army and Navy students will be accepted on completion of the Army or Navy premedical program. The course covers four academic years of nearly nine months each, but due to the accelerated program, the four year course is now completed in three calendar years. The fees average \$465 per academic year. The registration for 1942-1943 was 209, graduates, 52. The present session began March 24, 1943 and will end December 22, 1943, the following session begins January 3, 1944. The Dean is Waller S. Leathers, M.D.

TEXAS

Galveston

UNIVERSITY OF TEXAS MEDICAL BRANCH, 912 Avenue B—Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 61 professors (including associate and assistant professors) and 106 instructors and assistants, a total of 167. The Medical Branch is operating on an accelerated program offering three terms of 16 weeks each per calendar year to correlate it with the needs of the Army and Navy for medical education. The fees average \$92.50 per academic year, including health fees for medical care and hospitalization. The registration for 1942-1943 was 393, graduates, 87. The present freshman class was matriculated March 15, 1943. There will be a second freshman class to matriculate about November 1, 1943. The last class graduated July 31, 1943. Plans now call for the acceptance of new students about every eight months. The Dean is Chauncey D. Leake, Ph.D.

Houston

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 509 Lincoln Street, Houston, Texas—Organized in 1900 at Dallas as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. The school was moved to Houston in 1943. Coeducational since organization. The first class graduated in 1901. Entrance requirements are 80 semester hours of collegiate work. The course covers four years of eight months each. An accelerated program has been adopted beginning July 12, 1943, involving the admittance and graduation of a class every nine months. The fees are, respectively, \$423, \$413, \$403, \$428. The registration for 1942-1943 was 318, graduates, 77. The present session began July 12, 1943 and ends March 13, 1944. The Dean is W. H. Moursund, M.D.

VERMONT

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park—Organized with complete course in 1822. Classes graduated in 1823 to 1836 inclusive when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 37 professors and 45 instructors, and assistants, a total of 102. Army and Navy premedical curricula accepted for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. For residents of Vermont the tuition fee is \$160 each session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. The registration for 1942-1943 was 133 graduates, 31. The present session began April 12, 1943 and will end December 21, 1943. The subsequent session begins January 3, 1944. The Dean is Clarence H. Beecher, M.D.

VIRGINIA

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE—Organized in 1827. Classes were graduated in 1823 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. It has a faculty of 47 professors and 47 lecturers, instructors, assistants and others, a total of 94. Two years of college work are required for admission. For residents of Virginia the total fees average \$388 per academic year. Nonresidents are charged an additional \$50 each year. The registration for 1942-1943 was 113, graduates, 31. The present session began April 12, 1943 and will end December 21, 1943. The subsequent session begins January 3, 1944. The Dean is Clarence H. Beecher, M.D.

1943 was 258 graduates 55 The present session began March 29 1943 and will end December 20 1943 The subsequent session will begin December 29 1943 The Dean is Harvey Ernest Jordan Ph D

Richmond

MEDICAL COLLEGE OF VIRGINIA Twelfth and Marshall Streets—Organized in 1853 as the Medical Department of Hampden Sydney College Present title was taken in 1854 In 1913 the University College of Medicine was merged In 1914 the North Carolina Medical College was merged Coeducational since 1918 Classes were graduated in 1839 and in all subsequent years It has a faculty of 92 professors and 160 lecturers instructors and others a total of 258 Of this group 10 professors and 77 lecturers instructors and others are on military leave Two years of collegiate work are required for admission An accelerated program has been adopted involving the admission and graduation at a class approximately every nine months Fees average \$352 per academic year Nonresidents are charged an additional \$125 each year The registration for 1942-1943 was 300 graduates 68 The present session began April 5 1943 and will end December 22 1943 The subsequent session will begin December 30 1943 The Dean is J P Gray M D

WISCONSIN

Madison

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL 418 North Randall Avenue—Organized in 1907 Gave only the first two years of the medical course until 1925 when the clinical years were added Coeducational since organization The requirement of three years of collegiate work for admission has been reduced to two years for the duration Beginning July 1 1943 a class is being admitted every nine months An accelerated program has been adopted permitting the completion of four years of academic work in three calendar years It has a faculty of 64 professors and 67 lecturers instructors and others a total of 131 The fees average \$206 per academic year An additional fee of \$200 each year is charged nonresidents The registration for 1942-1943 was 277 graduates 63 The present session for freshmen began July 1 1943 and the following session will begin April 1944 The Acting Dean is Walter J Meek Ph D

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE 561 North Fifteenth Street—Organized in December 1912 by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons Coeducational since organization It has a faculty of 192 Three years of collegiate work are normally required for admission During the duration students are admitted in accordance with the prescribed Army and Navy programs The accelerated program will include three semesters each calendar year and complete the equivalent of four years of eight and a half months each in three calendar years The fees average \$450 per academic year The registration for 1942-1943 was 345 graduates 150 The present session began March 1 1943 and will end October 31 1943 The subsequent session begins November 1 1943 The Dean is Ehen J Carey M D

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE Edmonton—Organized in 1913 Coeducational since organization Has given the complete six year medical course since 1924 New course—three years premedical four years medicine one year internship for medical degree—has been offered beginning with the session 1942-1943 The faculty includes 23 full time and 45 part time professors instructors assistants and others a total of 68 Tuition for the second third and fourth years is \$257 50 for the fifth and sixth years \$267 50 The registration for 1942-1943 was 160 graduates 33 The present session (accelerated) began February 1 1943 and will end September 1 1943 All medical classes are accelerated The following session opens September 27 1943 The Acting Dean is John James Ower M D

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE Bannatyne Avenue Winnipeg—Organized in 1883 as Manitoba Medical College first class graduated in 1886 and a class graduated each subsequent year The college transferred all its property to the University of Manitoba in 1919 and assumed the present title Coeducational since organization The faculty includes 36 professors and 103 instructors and assistants a total of 139 Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university An accelerated program has been adopted The course extends over four years of eight months each and a hospital internship The fees average \$254 yearly The registration for 1942-1943 was 228 graduates 50 The present session began for first year August 21 second year March 29 third year April 5 fourth year April 12, and will end April 1944 December 18 1943 January 8 and January 15 1944 The Dean is A T Mathers M D

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE Morris Street Halifax—Organized in 1867 Incorporated as the Halifax Medical College in 1875 Reorganized as an examining faculty separate from the Halifax Medical College in 1885 In 1911 in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College the work of the latter institution was discontinued and a full teaching faculty was established by the university First class graduated in 1872 Coeducational since 1871 It has a faculty of 39 professors and 38 demonstrators lecturers and others a total of 77 9 of whom are in active service and are on leave for the

duration Requires for matriculation two years of arts The regular medical course covers four years and a hospital internship of one year In order to meet the needs of the Canadian Armed Forces the classes in the last three years have been accelerated The content of the third and fourth years remains the same but holidays have been practically eliminated The final year internship has for the time being been reduced to eight months The third year began their studies on May 10 and continue until the end of December The fourth year began their studies on January 4 and continue until the middle of August The first and second years will begin on September 8 1943 and end on May 11 1944 The fees average \$314 yearly \$250 additional registration fee payable by students outside the British Empire The registration for 1942-1943 was 171 graduates, 37 The Dean is H G Grant M D

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE Kingston—Organized 1854 first class graduated in 1855 and a class graduated each subsequent year The faculty numbers 65 Fees for the first year amount to \$231 and for the following years \$253 The course covers six years of thirty teaching weeks each An accelerated program has been adopted and the course may now be completed in four and one-half years Fresh men will be admitted annually The registration in September 1942 was 279 graduates during the session 1942-1943 45 The next session begins for second year students August 23, 1943 for first, fifth and sixth year students on September 27 1943 for fourth year students on January 3 1944 and for third year students on April 10 1944 Classes graduated July 28 1943 and another class will be graduated April 30 1944 The Dean is Frederick Etherington M D

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto—Organized in 1843 as the Medical Faculty of King's College Abolished in 1853 Reestablished in 1887 In 1902 it absorbed Victoria University Medical Department and in 1903 it absorbed the Medical Faculty of Trinity University Coeducational since 1903 The BSc (Med) degree is conferred at the end of the third or sixth year It has a faculty of 76 professors and 342 (including 81 on leave of absence for the duration of the war) lecturers associates and others a total of 418 The fees are \$240 for the first year for the second \$315 \$315 for the third year \$340 for the fourth and fifth years and \$358 for the sixth year The registration for 1942-1943 was 753 graduates 107 The next first year course begins September 28 1943 and ends May 6 1944 Students in the final year graduated July 30 1943 and will graduate every eight months thereafter The Dean is W E Galtie M D

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL Ottawa Avenue, London—Organized in 1881 as the Western University Faculty of Medicine first class graduated in 1883 and a class graduated each subsequent year Present title in 1923 The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913 Coeducational since 1913 The faculty numbers 101 The normal course of study covers five years of ten months each The total fees to residents of Canada for the last four years respectively are \$352 \$352 \$348 and \$252 nonresidents are charged \$642 \$642 \$638 and \$438 for each of the last four years The registration for 1942-1943 was 224 graduates 30 The next session begins for the sixth year August 30 1943 and ends April 15 1944 Classes for the second third and fourth years begin August 30 1943 and end June 17 1944 The Dean is F J H Campbell M D

Quebec

LAVAL UNIVERSITY FACULTY OF MEDICINE Quebec—The Quebec School of Medicine organized in 1848 became in 1853 the Laval University Faculty of Medicine first class graduated in 1855 and a class graduated each subsequent year An accelerated program was adopted in 1942 on account of the war The faculty numbers 91 The fees for each of the medical years are \$200 for residents of Canada Nonresidents are charged an extra fee of \$200 each year The premedical requirement is a B A degree or its equivalent The registration for 1942-1943 was 364 graduates 47 The next class will graduate in September 1943 Freshmen will enroll Sept. 1 1943 The Dean is Charles Vezeina M D

MCGILL UNIVERSITY FACULTY OF MEDICINE 3640 University Street Montreal—Founded in 1823 as Montreal Medical Institution became the Medical Faculty of McGill University in 1829 first class graduated under the university auspices in 1833 No session between 1836-1839 owing to political trouble In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College Coeducational since 1919 Three years of collegiate work are required for admission An acceleration program has been adopted for the upper classes The faculty consists of 82 professors and 204 lecturers and others a total of 286 The total fees for each of the four medical years are \$391 plus \$100 for non British subjects The registration for 1942-1943 was 409 graduates 94 The present session began for sophomores June 7 juniors February 17 and seniors May 6 1943 Freshmen will enroll September 7 1943 The next class will graduate November 1943 The Dean is J R Fraser M D

UNIVERSITY OF MONTREAL FACULTY OF MEDICINE 2500 Mount Royal Boulevard Montreal—Organized in 1843 as the Montreal School of Medicine and Surgery In 1891 by Act of Parliament the Medical Faculty at Laval University (organized in 1878) was absorbed Present name by Act of Parliament in 1920 A class was graduated in 1845 and each subsequent year Coeducational since 1925 The faculty numbers 150 The B A or B S degree or its equivalent is the premedical requirement An accelerated program has been adopted An internship is required for graduation The fees average \$235 yearly The registration for 1942-1943 was 237 graduates 53 The present session for juniors and seniors began June 1 1943 and will end Nov 30 1943 Freshmen and sophomores will enroll Sept. 1 1943 and will complete the year April 17 1944 The Dean is Albert LeSage M D

DESCRIPTION OF SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. Coeducational since 1920. Minimum entrance requirements meet Army and Navy specifications. An accelerated program has been adopted and a new freshman class will be admitted approximately every nine months. The faculty includes 14 professors and 14 instructors, assistants, and others, a total of 28 of whom 7 are absent in the Armed Forces. The tuition fees are \$154 each academic year plus \$75 differential for non residents. The registration for 1942-1943 was 99. The present session began March 11, 1943, and will end November 6, 1943. The subsequent session will begin December 6, 1943. The Dean is Stuart Graves, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE—Organized in 1903. Coeducational since organization. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. An accelerated program has been adopted and a new freshman class is admitted each nine months. Entrance requirement is three years of collegiate work or ninety semester hours of credit. The B.S. degree in medicine is conferred at the end of the second year. The faculty includes 9 professors, 2 assistant professors, 1 adjunct professor, 17 instructors, assistants and others, a total of 29. The total fees for the first year are \$375, and for the second year \$348. The registration for 1942-1943 was 58. The present session began February 1, 1943, and will end September 20, 1943. The subsequent session begins September 27, 1943. The Dean is B. S. Guyton, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE—Organized at St. Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. An accelerated program has been adopted involving the admittance of a class every nine months. The faculty includes 23 professors and 19 instructors, lecturers and others, a total of 42. The entrance requirements are 60 semester hours of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are \$266, for the second, \$224. The registration for 1942-1943 was 75. The current session began March 22, 1943 and will end December 18, 1943. The subsequent session will begin December 27, 1943. The Dean is Dudley S. Conley, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 22 professors and 14 instructors, a total of 36. Army and Navy premedical curricula accepted for admission. An accelerated program has been adopted admitting a freshman class approximately every nine months or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1942-1943 was 46. The present session began February 7, 1943 and will end October 23, 1943. The subsequent session begins October 31, 1943. The Dean is John P. Bowler, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department in Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of college work are required for admission. Certificates are awarded on the completion of two years work in medicine. The faculty is composed of 20 professors and 13 instructors, a total of 33. The fees for each year are \$300 for residents for nonresidents an additional fee of \$100. The registration for 1942-1943 was 91. The school has gone on the accelerated schedule for the duration of the war. The 1943 session began March 22 and new sessions will begin approximately every nine months. The next session will begin December 1943. The Dean is W. Reece Berryhill, M.D.

Winston-Salem

BOWMAN GRAY SCHOOL OF MEDICINE OF WAKE FOREST COLLEGE, WINSTON SALEM—Organized in 1902 at Wake Forest as a school offering only the first two years of the curriculum. In 1941 the school

was moved to Winston-Salem and expanded to a complete four year medical school under its present name. Ninety semester hours of college work are required for admission. For the duration of the present war students may be admitted who have completed only sixty semester hours. The B.S. degree is given to those who on admission have completed ninety semester hours of academic work after the completion of the first year in the medical school. Under an accelerated program classes are admitted every nine months. The next class will be admitted on January 3, 1944. The faculty numbers 119, 18 of whom are on leave of absence in active military service. Tuition for each academic session is \$450. Registration for the session 1942-1943 was 114. The present session began March 22, 1943 and will end in December 1943. The Dean is C. C. Carpenter, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years work in a college of liberal arts are required for admission. (For the duration of the war about two years as per Army and Navy plans.) The B.S. degree in combined arts medical course is conferred at the end of the second year. The faculty consists of 7 professors and 8 instructors, a total of 15. The fees are \$170 each year for resident students and \$340 for nonresidents. The registration for 1942-1943 was 53. The present session began June 14, 1943 and ends March 26, 1944. The Dean is H. E. French, M.D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Three years work in a college of liberal arts are required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A.B. degree. The faculty numbers 18. An accelerated program has been adopted involving the admittance of a class approximately every nine months. The tuition is \$150 each year for residents and \$250 for nonresidents. The registration for 1942-1943 was 49. The present session began March 8, 1943 and will end December 4, 1943. The subsequent session will begin December 6, 1943. The Dean is Joseph C. Ohlmacher, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE, University Street—Organized in 1906. Coeducational since organization. Four year course started in March 1943, when the first junior class began its work. The complete four year course is now in the process of being organized. An accelerated program has been adopted involving the admittance of a class every nine months. Three years of collegiate work are required for admission. The medical faculty consists of 16 professors, 3 instructors, 35 lecturers and 5 fellows, assistants and technicians, a total of 59. The fees for each quarter are \$135; there is a nonresident fee of \$55 each year. The registration for 1942-1943 was 79. The present session began March 20, 1943 and ends December 3, 1943. The subsequent session begins December 13, 1943. The Dean is A. Cyril Callister, M.D., C. B. Freudenberger, M.D., being Associate Dean.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE—Organized in 1902, gives the first two years of the medical course but agreement has been made for the transfer of 20 students each year to the Medical College of Virginia. Coeducational since organization. Entrance requirements are normally three years of collegiate work but a minimum of two years will be accepted when necessary during the war emergency. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance of a class every nine months. Faculty numbers 24. Fees for residents of the state are, respectively, \$225 and \$265; nonresidents \$150 additional each year. The registration for 1942-1943 was 56. The present session began March 22 and will end December 17, 1943. The subsequent session begins December 27, 1943. The Dean is Edward J. Van Liere, M.D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES—Organized in 1926. Coeducational. Offers the first two years of the medical course. An accelerated program has been adopted. Three years of collegiate work are required for admission. The B.S. degree is conferred at the end of the second year. The medical faculty consists of 7 professors and 4 lecturers and assistants, a total of 11. The fees are \$150 for each year. The registration for 1942-1943 was 44. The session begins October 5, 1943 for the first year and ends May 1, 1944. The second year began June 1, 1943 and ends December 2, 1943. The Dean is W. S. Lindsay, M.B.

INTERNSHIPS, RESIDENCIES AND FELLOWSHIPS

(Lists Available on Request see footnote 1)

In January 1943 the civilian hospitals approved for intern training could accommodate 7,959 interns. When compared with 5,567 actually on duty it is apparent that these hospitals were operating with a shortage of 2,392 interns. Under normal conditions, however, many of these vacancies would have been filled by interns continuing beyond the usual twelve months period. For example, in January 1942 there were 7,219 interns employed, or approximately 2,000 more than the number of medical graduates in the preceding year. In the face of this continuing shortage it is becoming increasingly important that hospitals cooperate in maintaining an equitable distribution of interns by limiting appointments to actual minimum needs. As a general rule the ratio of house officers to patients should not exceed one intern to six hundred annual admissions.

NEW INTERNSHIPS

Many hospitals that were formerly employing resident physicians as general house officers are now facing a dearth of resident personnel and are considering the possibility of establishing an intern training program. The main concern in such a plan is the ability of the hospital to fulfill the requirements of the fifth year of medicine for the internship is primarily an educational function and should not be viewed as a means of supplying personnel in relation to institutional service. It should also be taken into account that with the present scarcity of applicants it is unlikely that any new hospital entering the educational field will be able to attract a sufficient number of qualified medical graduates to establish and maintain a satisfactory rotating service. Prospective interns will naturally continue to seek appointments in hospitals whose educational services have long been established and are already favorably known. The 759 hospitals currently approved for intern training are supplying more internships than are required even under the present accelerated program of medical education.

LIMITATION OF DUTIES

With the present shortage of interns and residents economy in the use of house officers should be observed not only from a numerical point of view but also in relation to individual assignments. If possible, therefore, the routine procedures which do not contribute materially to the training program should be transferred to nursing and technical personnel so that the intern's time may be devoted to essential hospital and educational needs. Record work can often be reduced in volume without sacrificing any of the essential clinical data. In this manner considerable time can be saved as well as through the use of dictaphones and stenographic assistance whenever available. When operating with a limited house staff it might become necessary for the attending physicians to take over some of the duties ordinarily assigned to interns and residents. While this would seem difficult under present conditions, it should be noted that the elimination of parallel services, multiple emergency assignments and other duplications of staff efforts has made it possible in some hospitals to obtain at least a partial solution to this problem.

OVERLAPPING OF INTERNSHIPS

Under the present accelerated program of medical education there is considerable difficulty in coordinating the regular one year internship with a new graduating class every nine months. The main difficulty when graduation and internship periods do not coincide is the overlapping of services that will necessarily occur. Thus hospitals may experience alternate periods of shortage and overabundance of house officers with the attendant problems of housing and readjustment of schedules. Many hospitals, however, which do not have their full quota of interns can readily accept new applicants three months before the previous group has completed its year of service. Others may find a solution in the establishment of affiliated services in neighboring hospitals that are prepared to offer satisfactory

training. If this method is adopted, the educational assignments should be carefully planned in relation to the total internship program of the individual graduate. It should also be noted that only when a hospital is prepared to assume supervision and responsibility for the affiliated three months training will it be in position to certify the completion of the required twelve months internship. Because of the shortage of residents it has also been possible in some institutions to give the senior interns advanced houseships during the last three months so that their work will not conflict with the assignments of the incoming group. A few hospitals are planning to assign interns to senior staff physicians in their last three months of service. Such preceptorships should be under the supervision of the hospital intern committee and so correlated with the previous training as to furnish a well rounded internship program.

In some parts of the country it has been advocated that the internship be reduced to nine months. Hospitals, however, would still be confronted with the

1 Government wartime restrictions on the use of paper necessitates omission of the Council's revised list of approved internships, residencies and fellowships. However, copies of the lists will be printed and sent to all approved medical schools, medical libraries, approved hospitals, state licensing bodies, specialty boards and other interested agencies. The lists will also be included in the reprint edition of the Educational Number which has a wide distribution and is available on request.

problem of organizing internships in relation to the various dates of graduation. Furthermore, the need for giving medical students the full experience of a twelve months internship seems even greater now that the undergraduate curriculum has been compressed into a shorter time period. The Council on Medical Education and Hospitals, the Association of American Medical Colleges, the Army and the Navy have all recommended that the internship should not be reduced below the level of twelve months. Six medical schools require the completion of an internship before the degree of doctor of medicine is awarded. Twenty-two states, the District of Columbia, Alaska, Hawaii and Puerto Rico have a similar requirement in relation to licensure, and in some ten states the medical practice acts specify that applicants must have completed an intern service of at least one year. Any reduction, therefore, in the customary one year assignment would necessitate legislative change in these particular states in order that the interns might be eligible for licensure.

RESIDENCIES AND FELLOWSHIPS

In January 1943 the hospitals approved for residency training were offering 3,323 residencies, 1,762 assistant residencies and 711 fellowships, a total of 5,796. At that time 4,082 positions were filled, indicating a shortage of 1,714 in comparison with the number of applicants desired. Reference should be made to the accompanying table showing the present classification of approved residency training programs.

Because of military requirements it has been indicated that civilian hospitals will need to reduce their resident staff to less than 50 per cent of the number employed before the war. Residencies and fellowships, therefore, should be limited to such assignments as are essential for the provision of adequate hospital care and for the clinical training of medical students. When vacancies exist it has been recommended that essential residencies be filled by women physicians, men physicians disqualified for military service, other interns or residents deferred by Selective Service and qualified graduates of foreign medical schools.

While curtailment of civilian residencies must necessarily take place, it is encouraging to note that opportunities are being provided for continued specialty training in army and naval hospitals for which credit

may be assigned in accordance with the regulations of the individual certifying boards. Many of the hospitals of the Army Air Forces, for example, have recently established well organized residency training programs under the direction of the Air Surgeon's Office. These educational services, which may extend over a period of one year, have been found to fulfill the standards of the Council on Medical Education and Hospitals and have been approved as offering acceptable residencies in medicine and in surgery.

POSTWAR NEEDS

It is anticipated that immediately after the war large numbers of physicians will be seeking opportunities for graduate or postgraduate training in medicine. Many will wish to resume courses interrupted by the call to military service, while others will enter new training programs to prepare themselves for specialty practice.

To help meet this demand the Council has initiated a preliminary survey to determine all available and potential facilities for advanced training in connection with intern and residency hospitals, undergraduate and graduate medical schools, clinics, departments of health, state medical associations and other agencies interested in graduate or postgraduate education.

A total of 1,267 institutions and agencies included in this survey were asked to indicate what educational opportunities might be available if additional needs should develop. Information was requested primarily in relation to residency and fellowship training, basic science instruction, public health education and postgraduate courses in the various divisions of medicine and surgery. It was recognized that there would be opportunities for the development of additional high grade training programs in institutions that had not yet reached their full educational capacity. However, the Council did not wish to encourage the organization of new residencies, fellowships and postgraduate courses unless satisfactory facilities could be provided.

Replies have now been received from 682. While these have not yet been tabulated and analyzed, it is apparent from individual reports that genuine interest has been created and that institutions are anxious to cooperate to the full limit of their facilities. The Council is continuing its study of the opportunities for postwar graduate medical education.

CONTINUATION STUDY FOR PRACTICING PHYSICIANS

Realizing that many scientific meetings and other programs of graduate medical education have been canceled because of war conditions, the Council on Medical Education and Hospitals has endeavored, nevertheless, to provide information regarding opportunities still available for the continuing education of practicing physicians as well as medical officers in the armed forces. It has published quarterly in *THE JOURNAL* during the past year opportunities currently available. The last such listing appeared in *THE JOURNAL* for July 3, 1943. The next will appear in a September issue. These courses have proved valuable for physicians returning to practice in the present emergency as well as for those formerly limiting their practice to a specialty but who are now assisting in the general care of patients. In presenting this material, mention is made of recent and noteworthy developments in graduate education.

Graduate and postgraduate courses have been subdivided into three groups: courses in which instruction was offered to physicians in or near their home communities, courses providing ample facilities for clinical instruction and, lastly, a group including clinical conferences, graduate assemblies, study courses and so forth.

RECENT NOTEWORTHY DEVELOPMENTS

Under the auspices of the committee representing the American Medical Association, the American College of Physicians and the American College of Surgeons, a series of War-Time Graduate Medical Meetings is being developed. These programs have been organized for physicians in the Army, Navy and Public Health Service and for physicians in civilian life who are resident within reasonable traveling distance of the camps and hospitals in which these postgraduate oppor-

tunities will be offered. For organizational purposes the country has been divided into twenty-four sections, and key committees of three men have been appointed in each section to carry on the details of the program. In order to insure the best results a group of qualified authorities has been designated to serve as national consultants in the various special fields. Likewise the Surgeon Generals of the Army, Navy and Public Health Service have appointed a committee of three one man from each organization to collaborate in the work of administration. This program is essentially an elaboration of a teaching plan that has been used successfully in the Boston, Chicago and Philadelphia areas, originated by the American College of Physicians. Arrangements have been made with fifty-five medical schools to participate in these teaching programs. The section committees in conferences with commanding officers of service hospitals in their areas are selecting subjects, dates and teaching personnel for graduate courses. A directive was issued from the office of the Surgeon General of the Army calling the attention of commanding officers to this educational project and urging their cooperation and active participation. Tentative programs have appeared in *THE JOURNAL* of June 5, June 26 and July 3.

A preliminary survey has been initiated by the Council on Medical Education and Hospitals of the American Medical Association to determine all available and potential facilities for advanced postwar training in connection with hospitals, undergraduate and graduate medical schools, clinics, departments of health and other agencies interested in graduate or postgraduate education. It is anticipated that large numbers of physicians will be seeking such opportunities. Many will wish to resume courses interrupted by entrance into military service while others will enter new training programs to prepare themselves for specialty practice. It is recognized that there will be opportunities for the development of additional high grade training programs in institutions which have not yet reached their full educational capacity. An analysis of questionnaires sent out for this purpose is now being made by the Council.

Courses for medical officers of the Army, Navy and Public Health Service have been given repeatedly throughout the year. In addition the Public Health Service has arranged courses of six months to three years duration throughout the United States in the diagnosis and treatment of cancer for civilian physicians. Lectures sponsored by the Public Health Service and other agencies in occupational dermatoses have been held at the National Institute of Health. These facilities were available to physicians, specialists and naval medical officers. In Chicago the Dermatoses Investigation Section of the Public Health Service offered without charge to physicians a two weeks course, clinical and didactic in nature, in occupational dermatoses using the facilities of industrial plants.

Eight universities were given subsidies by the United States Public Health Service to provide opportunities for instruction in public health including venereal diseases. These courses vary in length from three months to one year and were given throughout the year. Of these eight universities which were given subsidies, only five were active in providing these courses. The total attendance was fifteen. Weekly since June 15 the Public Health Service and the Philadelphia Lying-In Hospital have given clinical courses in continuous caudal anesthesia, with a weekly attendance of seven

The four week course annually offered in the fall and spring at Hot Springs National Park by the Public Health Service in the clinical management and public health control of the venereal diseases was again offered during the past year. This course was made available to sixty-eight physicians and no fee was charged.

Financed by the Western Association of Industrial Physicians and Surgeons, the California State Board of Health and the California Medical Association, didactic courses in wartime industrial health were offered in seven centers. No fee was exacted, and the courses covered one day in the autumn of the year.

At Yale University School of Medicine one session a week for twelve weeks was devoted to industrial health and medicine in wartime, with a total attendance of sixty-one physicians.

Again during the past year the Georgia Warm Springs Foundation offered instruction in poliomyelitis, the course being of one week's duration.

The Institute for Psychoanalysis in Chicago, together with the University of Illinois and the Michael Reese Hospital has developed three courses in psychiatry and neurology emphasizing war neuroses varying in length from two weeks to four months. The physician attendance at these courses throughout the year totaled 145.

The twenty-seventh annual assembly of the Interstate Postgraduate Medical Association of North America was held in Chicago. The assembly occupied a five day period devoted to both clinical and didactic instruction. The recorded attendance at the assembly was 2,500.

Arranged short courses as well as courses up to one year's duration, both clinical and didactic in nature, were available at the Menninger Foundation, Topeka, Kans., in psychiatry and neurology. The Topeka Psychoanalytic Society and the Southard School in that city cooperated in this endeavor in some instances.

The Maine Medical Association, together with the Bingham Associates and the Commonwealth Fund, arranged courses varying in length up to two months.

A three week course in industrial medicine was given to physicians in Michigan without fee by the Michigan Department of Health in collaboration with the Michigan State Medical Society, the Council on Industrial Health of the American Medical Association, the Social Security Agency and the Procurement and Assignment Service.

At the Center for Continuation Study at the University of Minnesota, in cooperation with the National Foundation for Infantile Paralysis, two courses were offered in the Kenny method of treatment of poliomyelitis. One course of five days duration was offered in the autumn of 1942 and the summer of 1943. A course six days in length was offered on seven occasions also at the Center for Continuation Study. A registration of 214 physicians was reported for these courses. The fee charged was \$25. These courses are in addition to the complete program of graduate studies offered in various subjects at the Center.

Courses in obstetrics and pediatrics consisting of one day in each of eleven centers, given in the autumn of the year were offered by the University of Nebraska College of Medicine and the Nebraska State Department of Health.

The West Virginia Medical Association and Department of Health conducted one day industrial health institutes in each of four centers of the state.

Industrial apprenticeships of one day's duration were sponsored by the Long Island College of Medicine. The facilities of industrial plants in various states were used under the direction of a director of preventive medicine and community health.

The excellent opportunities heretofore offered by organized graduate schools were again presented in various subjects at such institutions as Tulane, Hopkins, Harvard, Tufts, University of Michigan, the Center for Continuation Study of the University of Minnesota, Buffalo, Columbia, New York Eye and Ear Infirmary, New York College of Medicine, New York University, the New York Polyclinic, the University of Pennsylvania and many others.

These examples emphasize the fact that even though the staff physicians of all institutions are sorely taxed, they have been able to develop or continue opportunities for graduate education, many of which have not been mentioned. The Council welcomes information regarding graduate education for publication in its quarterly compilation of courses.

ANALYSIS OF COURSES OFFERED, 1942-1943

At least sixteen states provided opportunities for physicians to continue professional study in or near their home communities. Courses on industrial problems in medical practice were most commonly in demand, although opportunities were presented in obstetrics and pediatrics, internal medicine and tuberculosis as well as courses of interest to the general practitioner. In addition, courses of one day's duration in the treatment of gonorrhea were given by the West Virginia Department of Health and the United States Public Health Service in sixteen centers in West Virginia. The War Sessions of the American College of Surgeons, consisting of a full day's program, were available in the winter and spring months in twenty cities throughout the United States. All together, these programs were given in more than eighty centers.

Agencies which were active participants in providing these opportunities either independently or jointly included committees on graduate medical education of state and county medical societies, state departments of health, medical schools and graduate schools of medicine. Other agencies were industrial and tuberculosis associations, industrial concerns, the Commonwealth Fund, the United States Public Health Service, the United States Army, the United States Navy, the Social Security Agency, the Procurement and Assignment Service and the Council on Industrial Health of the American Medical Association.

The courses varied in length from two evening sessions to a full month of work. Sessions of one day were most common and consisted of both didactic and clinical instruction in most instances. The instructors for these extramural courses were chosen from physicians practicing in the state in which the courses were offered as well as from out of state men. The faculties of four medical schools made a large contribution to this type of instruction. The facilities used consisted of hospitals, clinics, medical schools, industrial plants and local buildings. No fee was charged in the majority of instances. The War Sessions of the American College of Surgeons attracted 14,000 physicians. The attendance reported for other opportunities was well over 4,500.

Home study courses were made available by three cities: two courses in ophthalmology and otolaryn-

gology of nine months' duration, a year's course in public health and four courses on various subjects. These home study courses were offered by the American Academy of Ophthalmology and Otolaryngology, the Maine Medical Association and the Albany Medical College in collaboration with the New York State Department of Health. The facilities reported were the public mails and physicians' homes, while in the third instance physicians' homes, laboratories, hospitals and the medical school were used. The instruction included selected readings, quizzes, didactic work and clinical field trips. An enrollment of 265 was reported for the courses given by the American Academy of Ophthalmology and Otolaryngology. Fifty-nine physicians availed themselves of the opportunities afforded by the Maine Medical Association and fifty students were enrolled in the home study course of the Albany Medical College.

In centers where ample clinical facilities are available, 440 graduate courses of less than one year's duration were offered in twenty-three states and the District of Columbia. Eighty-three agencies or combinations of agencies participated in the planning of the programs. Of the medical schools of the country, thirty-five have given courses for practicing physicians during the year, including nine postgraduate schools or graduate departments of medical schools. Five state medical societies and eight state or local departments of health collaborated on courses or independently planned courses for physicians of the state. In nine instances hospitals were the agencies offering short periods of study. Other sponsors included three county medical societies, five special societies, the Office of Civilian Defense, the Public Health Service, the Children's Bureau of the Department of Labor, the Commonwealth Fund and more than ten other miscellaneous agencies. While the majority of courses were in various subjects as the demand seemed apparent, specific courses in ophthalmology and otolaryngology were offered in fifty-six instances, general medicine in thirty-five, obstetrics and gynecology and dermatology and syphilology both in thirty instances, military medicine in twenty-six, both surgery and gastroenterology in twenty-three, public health in twenty-two and psychiatry and neurology in twenty instances. More than ten but less than twenty courses were offered in anesthesiology, cardiology, electrocardiology, orthopedics, pathology, pediatrics, roentgenology and tuberculosis. Other courses were offered in allergy, anatomy, bacteriology, cancer, chemical warfare, diagnosis, dietetics, endocrinology, endoscopy, general practice, hematology, industrial medicine, legal medicine, physical therapy, physiology, poliomyelitis, proctology, tropical medicine, urology, venereal diseases and two which were not stated. Fifty-six definite centers in these twenty-three states were used in presenting these 440 courses, excluding the facilities made available by the Navy, the Public Health Service and the National Institute of Health. Notably, courses were offered in eleven centers in one state and in eight in another state. In presenting graduate courses, thirty-nine hospitals, thirty-eight medical schools and twenty-four clinics cooperated by placing their facilities at the disposal of instructors and students. The description of these intensive courses gave evidence that clinical instruction was emphasized. In only three instances was the work wholly didactic. The faculties of the medical schools served as instructors in most courses. Additional instructors were specialists in their fields.

chosen mainly from physicians residing within the state in which the course was offered, but including as well physicians from outside the state. The duration of study in centers with clinical facilities varied from five days to one year. The majority, however, were completed within three weeks. The number registered for any one course ranged from 1 to 2,500. In seven instances the attendance was well over 200. The attendance reported, although incomplete, totaled 8,786.

Clinical conferences, graduate assemblies and study courses of less than five days were held in nineteen states. Fifty-two such opportunities were afforded. This type of study was sponsored by eleven medical schools, six state medical societies, ten county medical societies, twenty-three special societies, seven state and local governmental agencies, two hospitals, the United States Public Health Service, the Office of Civilian Defense and nine miscellaneous agencies. A specially appointed director or the clinics or chairman of the committee was responsible for most of the courses. The nature of these study courses was mainly subjects allied to war medicine, including the medical aspects of chemical warfare, aviation medicine and tropical medicine. Opportunities were also afforded in

public health, cardiovascular diseases, glaucoma, industrial health, pediatrics, health education, anesthesia, obstetrics and venereal diseases. Other assemblies surveyed pertinent topics in medicine and surgery. The assemblies were usually held in centers large enough to accommodate the registrants and with facilities for clinical and practical work and for scientific exhibits. In one state instruction was offered to medical officers of the Army and Navy in four military centers, while a three-day course was offered in another state. In addition the American College of Physicians held wartime regional meetings in eight states and the District of Columbia and also conducted postgraduate nights in two states, both of which were available to members of the College and medical officers of the armed forces.

Here again the instruction was both didactic and clinical in the majority of instances. The instructors consisted of physicians residing in the state wherein the assembly was held, physicians from other states and members of the professorial faculties of medical schools. Registration fees ranged from \$2 to \$25, but for the most part no fee was charged. The largest single attendance reported was 2,453. The total recorded attendance was 15,301.

APPROVED EXAMINING BOARDS IN MEDICAL SPECIALTIES

In 1933 the Council on Medical Education and Hospitals of the American Medical Association was authorized by the House of Delegates of the American Medical Association to formulate standards and approve examining boards in the medical specialties. The resolution urged that the machinery of the American Medical Association, including the publication of the American Medical Directory, be used in furthering the work of boards accredited under this plan.

Standards governing the approval of specialty boards were compiled by the Council and approved by the House of Delegates in 1934 and have since been revised. The Essentials of Approved Examining Boards in Specialties include, in addition to regulations relating to the organization and operation of specialty boards, the minimum qualifications deemed necessary for certification as a specialist, namely, graduation from a medical school approved by the Council on Medical Education and Hospitals, an internship in a hospital approved by the Council, and a period of specialized training in a selected field.

Fifteen boards have now been organized. These boards are fully approved by the Council and represent the specialties of anesthesiology, dermatology and syphilology, internal medicine, neurologic surgery, obstetrics and gynecology, ophthalmology, orthopedic surgery, otolaryngology, pathology, pediatrics, plastic surgery, psychiatry and neurology, radiology, surgery and urology. The American Board of Internal Medicine by special examination certifies specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis. Similarly the American Board of Surgery certifies specialists in proctology.

A key number has been assigned to each approved specialty board, such as A B I, and the biographic records of physicians published in the American Medical Directory include by this means reference to those certified by these boards.

Early in 1939 there was published by the Advisory Board for Medical Specialties the first edition of the Directory of Medical Specialists containing the names and biographic data of all men certified by the several specialty boards as well as information regarding the organization and functions of these boards. The second edition appeared early in 1942 and contains the names of about 18,000 certified specialists, including their biographic records and hospital and teaching appointments.

Total Numbers of Certificates Awarded by the Specialty Boards to March 1, 1943

Name of Board	Certificates Awarded
American Board of Anesthesiology	183
American Board of Dermatology and Syphilology	644
American Board of Internal Medicine	2,965
American Board of Neurological Surgery	135
American Board of Obstetrics and Gynecology	1,676
American Board of Ophthalmology	2,195
American Board of Orthopaedic Surgery	819
American Board of Otolaryngology	3,570
American Board of Pathology	954
American Board of Pediatrics	1,959
American Board of Plastic Surgery	157
American Board of Psychiatry and Neurology	1,520
American Board of Radiology	1,923
American Board of Surgery	2,144
American Board of Urology	942
Total	21,733

ments. Since that time, nearly 4,000 additional physicians have been certified. The accompanying table shows the distribution of these specialists among the boards.

Each of these boards has published a booklet containing a brief statement regarding its organization, personnel, purposes and qualifications for eligibility for certification. In addition, some of the boards publish lists of specialists they have certified. Booklets and lists and other data on examinations may be obtained from the secretaries of the various boards, whose addresses are given herewith.

Under the present policies of the Procurement and Assignment Service (see p 1093) an even greater reduction in numbers of men permitted to take residencies is to be expected. It is stipulated that residencies may not be taken for training purposes, in the case of young men qualified for military service. Any such residents must be essential as teachers or house physicians. This will greatly curtail the numbers of men preparing for specialty certification. Consideration to this problem is being given by the specialty boards, which are granting some credit toward certification for work carried by a medical officer in the armed forces. A summary of the present policies is given for each of the boards listed. In announcing these policies, the boards state that requirements will not be lowered because of war conditions.

It is highly important that prospective applicants who are in military services should obtain a copy of the "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" from the secretary of any board. This booklet describes procedures pertaining to military credit and will enable prospective applicants and candidates to keep an accurate account of work done in the military service and will constitute part of the credentials to be submitted to the board on application for certification.

AMERICAN BOARD OF ANESTHESIOLOGY

President JOHN S LUNDY, M D, Rochester, Minn

Secretary PAUL M WOOD, M D, 745 Fifth Avenue, New York

"To officers who are practicing anesthesia in the armed services, the American Board of Anesthesiology allows the actual time up to one year credit for training. If they are not practicing anesthesia in service, they are allowed no credit for training but may be allowed up to a maximum of one year credit for practice in anesthesiology toward the five year time requirement. If practicing anesthesia in service the candidate is allowed actual time credit towards the five year practice in anesthesia time requirement."

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY

President HOWARD FOX, M D, New York, N Y

Secretary C G LANE, M D, 416 Marlboro Street, Boston

"The amount of credit for military service so far as training in this field is concerned will be decided in each case upon the evidence submitted by the candidate. Three years of full time training are required, and up to the present time no center in either Army or Navy has been developed where satisfactory training in this field may be obtained.

"So far as experience in dermatology and syphilology is concerned, the board will accept not more than one year of Army military or naval medical service as part of the required two years' experience, after the three years of training. For an officer who has completed or nearly completed his training in civil life, it is expected that the medical officer will file his 'Record of Professional Assignments' with his application as evidence of his service in the specialty."

AMERICAN BOARD OF INTERNAL MEDICINE

Chairman ERNEST E IRONS, M D, Chicago, Ill

Assistant Secretary W A WERRELL, M D, 1301 University Avenue, Madison, Wis

"One year of service in the armed forces may be considered as one year of formal training or as one year in the practice of medicine. Further evaluation of service in the armed forces will be made after the emergency is over."

AMERICAN BOARD OF NEUROLOGICAL SURGERY

Chairman HOWARD C NAFFZIGER, M D, San Francisco, Calif
Secretary-Treasurer PAUL C BUCY, M D, 912 South Wood Street, Chicago

"The amount of credit to be allowed for training received while with the armed forces will be determined in each individual case by the board on the basis of the extent and nature of the training received. The only blanket concession which the American Board of Neurological Surgery has made in the cases of men in the armed service, is as follows. The Charter and By-Laws of the American Board of Neurological Surgery, Article 4, Section 1, Group B (c), page 16, states 'an additional period of not less than two years in the practice of neurological surgery' shall be required following the three year period of training in neurological surgery before the individual will be admitted to examination by the board. The board has waived this two year practice requirement and now permits men to take the examination immediately after completing the three year period of training in neurological surgery. However, men who have taken the examination under such circumstances and passed it, will have their certificates withheld by the board until they have given the board satisfactory evidence of having completed two years of practice in neurological surgery. Such practice may be in an institution, private, or in the armed services, providing that it meets with the approval of the board and is practice in neurological surgery, and not general surgery or some other specialty. This action was taken in order to permit the board to place its stamp of approval upon the training these young men have received and upon what they had learned in order that the surgeon generals of the various armed services may make the most possible use of their abilities."

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

President WALTER T DANNREUTHER, M D, New York, N Y

Secretary PAUL TITUS, M D, 1015 Highland Building, Pittsburgh 6, Pa

"An applicant in military service in the present national emergency and assigned to work in general surgery under conditions acceptable to the credentials committee may receive credit up to a maximum of six months applicable toward his three required years of special training. An applicant in service under military orders in an Army or a Navy hospital under supervision in an obstetrical and/or gynecological service will be given the same credit as if he were working under a preceptor, since most of these departments are supervised by men who are diplomates of this board or who are recognized obstetrician-gynecologists. Additional time in military service with any type of general medical assignment may be applied toward the board's years in practice requirement."

AMERICAN BOARD OF OPHTHALMOLOGY

Chairman CONRAD BERENS, M D, New York, N Y

Secretary JOHN GREEN, M D, 6830 Waterman Boulevard, St Louis

"The amount of credit for military service is determined in each individual case, depending entirely upon the amount and type of ophthalmology done while in service. In evaluating credentials much depends on the size of the hospital and whether the work is supervised by responsible ophthalmologists."

AMERICAN BOARD OF ORTHOPEDIC SURGERY

President PHILIP D WILSON, M D, New York, N Y

Secretary G A CALDWELL, M D, 3503 Prytania Street, New Orleans

"During the present national emergency, credits up to a maximum of two years may be allowed for experience gained in surgery and orthopedics while serving with the armed forces. Credits will be given only upon presentation of evidence that such

service has, in the opinion of the Committee on Eligibility, been equivalent to similar periods of approved hospital training. Record of all such military service should be kept in the Record or Professional Assignments prescribed by the Advisory Board for Medical Specialties and submitted with his application.

(a) A year of orthopedic experience with the armed forces may be accepted to replace one of the three required years of orthopaedic resident training.

"(b) A second year of orthopedic service with the armed forces may be credited as a year toward the practice requirement."

AMERICAN BOARD OF OTOLARYNGOLOGY

President HARRIS P MOSHER, M.D., Marlborough Mass
Secretary D M LIEBLE, M.D., University Hospital Iowa City

"Credit for training received while in the armed forces will be governed by the merits of the individual case and will be determined by the credentials committee. Such credit is given for the time actually spent in restricted practice of otolaryngology."

AMERICAN BOARD OF PATHOLOGY

President A H SANFORD M.D., Rochester, Minn
Secretary F W HARTMAN M.D., Henry Ford Hospital, Detroit.

"Credit is allowed for training and experience in pathology as it may be acquired by the applicant during his military service. This credit for training or experience or both is given on an individual basis and will depend upon the opportunity the applicant has had as indicated in his medical service record in the specialty of pathology."

AMERICAN BOARD OF PEDIATRICS

President EDWARD B SHAW, M.D., San Francisco, Calif
Secretary C A ALDRICH, M.D., 707 Fullerton Avenue, Chicago

"Applicants are allowed credit for one year of military service toward the required two years of specialized practice. Military service cannot be substituted for preliminary training."

"Written examinations may be taken in camp under a Monitor, appointed by the commanding officer but the applicants must appear before the board for oral examination."

AMERICAN BOARD OF PLASTIC SURGERY

Chairman JOHN STANGE DAVIS M.D., Baltimore Md
Acting Secretary V P BLAIR, M.D., 508 North Grand Boulevard, St. Louis

"A man assigned to do plastic surgery in the armed forces, under suitable conditions, would be given credit toward requirements for the time thus spent, the final amount of credit in each individual case to be left to the discretion of the board and determined by the board after the information is submitted."

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

President C MACFIE CAMPBELL, M.D., Boston Mass
Secretary WALTER FREEMAN, M.D., 1028 Connecticut Avenue NW, Washington, D C

"A maximum of two years of appropriate military service is allowed in lieu of experience, two years being the minimum time required as experience. A maximum of one year of military service is allowed in lieu of training, three years of training being required."

AMERICAN BOARD OF RADIOLOGY

President G W HOLMES, M.D., Boston, Mass
Secretary BYRL R KIRKLIN, M.D., 102-110 Second Avenue SW, Rochester, Minn

"Full credit is allowed for all work done in an approved x-ray department of the Army, Navy or Marine Corps."

AMERICAN BOARD OF SURGERY

Chairman ARTHUR W ELTING, M.D., Albany, N Y
Secretary J STEWART RODMAN, M.D., 225 South Fifteenth Street, Philadelphia

"Officers in either branch of the service are given one year's credit on the necessary five years' training required. Further credit will depend in individual instances upon the assignments and must be surgical in nature in order to be acceptable."

AMERICAN BOARD OF UROLOGY

President HERMAN L KRETSCHMER, M.D., Chicago, Ill
Secretary G J THOMAS, M.D., 1409 Willow Street, Minneapolis

Applicants who join the armed forces before they have had the required two years of private practice are accepted as candidates for the examinations without immediate fulfillment of this requirement. When other requirements are satisfactorily fulfilled and the members of the credentials committee are convinced that the candidate has had sufficient training they may recommend that he submit to the written, pathological and oral-clinical examinations after he has submitted twenty-five acceptable case histories that he has personally examined, operated upon and followed while a senior resident. A candidate handled in this special manner will not become a certificatee until such time as he is able to complete the balance of the requirements, that is two years of private practice following the completion of his training in the specialty and the preparation of an additional twenty-five acceptable case histories taken from this private practice.

The members of this board have not established a precedent nor rigid specifications concerning the amount of credit allowed to candidates in the armed forces in lieu of training or private practice.

Candidates who have completed as many of the requirements for certification as possible and who have taken the examinations will be furnished statements carrying the official seal of the board outlining their status as candidates for certification."

ADVISORY BOARD FOR MEDICAL SPECIALTIES

President WILLARD C RAPPLEE, M.D., New York N Y
Secretary C G LANE, M.D., 416 Marlboro Street, Boston

Organized 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada this board reports directly to its member groups, and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association and with the Advisory Council on Medical Education.

SATURDAY, AUGUST 14, 1943

MEDICAL EDUCATION IN WARTIME

The medical students of the United States, almost all of whom have Army or Navy affiliations, are soldiers and seamen in medical school. They swell the numbers of uniformed men assigned to colleges and universities to pursue a wide variety of studies in preparation for special military duties. In one important respect, medical students will differ from most of their campus mates in uniform. Essentially they will be following the same curriculum and will receive the same degree for the same work as in peacetime. The Army and Navy have recognized that the wartime task of medical schools is the training of physicians and that this task, even as it pertains to the production of medical officers, can best be accomplished by a continuation of the well established medical program. The major change is acceleration, this was inaugurated even before Pearl Harbor and eliminates from the medical curriculum little except the long summer vacation.

In the collaborative educational-military responsibility of producing medical officers, by common agreement the military is wisely subordinated to the educational. Purely military instruction and drill are kept at a minimum. In all Navy units and in almost all medical schools so far under Army contract students live and eat where they please. Study is not abruptly terminated by taps. Common mess does not dictate the premature conclusion of an experiment or the physical examination of a patient.

Numerous courses inaugurated or especially stressed since the war began represent emphasis on topics which will justify their permanent inclusion in the medical curriculum. The shrinking of world distances through modern methods of transportation will bring tropical diseases to our doors. Industrial medicine and public health will increase in peacetime. Chemotherapy and the control of shock are not limited to war.

There are continuing tendencies away from clinical didactic teaching and also from the subdivision of medicine into isolated compartments. The line between preclinical and clinical is being less sharply drawn.

Interdepartmental collaboration in the presentation of related material is replacing a philosophy of medical education which states that the human body may be divided into its anatomy, its biochemistry, its pathology and its physical diagnosis. It is encouraging to note that the stress of the accelerated program has not prevented depleted faculties from a critical scrutiny of past performance and planning for means to improve the presentation of that most complex of subjects, man, in health and in disease.

Problems of postwar adjustments in medicine deserve inclusion in the undergraduate curriculum of more schools. How, if at all, is the practice of medicine likely to be different from that of the past? How may we arrive at a sound evaluation of the innumerable plans and proposed laws for improved medical care projected by lay and medical groups? These and related questions are being asked by medical students everywhere. A knowledge of the facts and analysis of the factors, forces and mechanisms at work, and the application of the searching scientific spirit which is the foundation of medical education, may lead more promptly to workable and acceptable methods.

PREMEDICAL EDUCATION

The accelerated programs developed by the armed forces for the training of premedical students differ in two essentials from the accelerated programs of the medical schools. First, acceleration in medical schools does not involve any basic change except the elimination of the long summer vacations. A significant increase in weekly work by the student is not required. The premedical programs, however, shorten the program mainly by a weekly increase in the quantity of work carried by the student. The Army Specialized Training Program provides for approximately 60 per cent more work per week by the student than in peacetime programs, and the Navy V-12 program also increases the weekly work considerably. Whether or not students will be able to carry this heavy load remains to be seen. These students will, however, be free from financial worries and the necessity for outside employment. They will receive medical care, and more attention will be paid to the students' physical condition.

The results of this experiment in concentrated premedical education will be watched with interest by all who are concerned with preprofessional education in every field, since it may offer a solution of the problem of reducing the long years of training required by the learned and scientific professions.

Second, all premedical students are subjected to a standardized curriculum. This is probably necessitated by the large number of participating premedical institutions, in some of which an attempt at standardization might elevate standards. By contrast, the medical curriculum prescribed by the armed forces is "do the best

you know how, as you have been doing." Such liberty can probably be granted only to educational institutions whose quality and programs of instruction have been well established.

The criticism has been made that the premedical programs are too heavily weighted with "tool" courses of purely utilitarian value and that they are deficient in human values. The justification for this criticism may be questioned. Properly presented, the natural sciences are rich in human values. Honesty and integrity in science are as rigorous as the tenets of any ethical system. A carefully controlled scientific experiment, testing deductions from a hypothesis, is as illustrative of correct thinking as are syllogisms and inductions of formal logic. The history of science and scientists incorporates fully as much of cultural values as does political, economic or military history. It would be preposterous to maintain that the natural sciences alone can provide a liberal education, it is even more obtuse to argue that these sciences lack human values.

THE SUPPLY OF PHYSICIANS

More than 4,000 seniors who entered the accelerated medical education program over a year ago are now well into their intern year and will complete that training before March 31, 1944. They will thus become available for military and civilian practice three months earlier than in normal times. Even half of these should only that small proportion be commissioned can care medically for over 300,000 troops. If this number of men is thereby enabled to enter active service three months early, before April of next year, the accelerated program will have justified itself in supplying the men required. All medical schools are accelerating throughout the four year program except one which limits the program to the junior and senior years. All are admitting classes every nine months except one which admits a class every year and one which admits a class each quarter.

A study of the number of graduates in the past forty years reveals trends of interest and importance. During approximately the first half of this period the number of graduates declined from over 5,000 annually to about half that number. This reduction paralleled the closing of many medical schools, one half of which disappeared during the period of enforcement of high standards in medical education. During the last two decades the number of graduates gradually rose, even before the war it again exceeded 5,000. This occurred in spite of an essentially unchanged number of medical schools. In 1942 there were about as many graduates from seventy-seven high grade schools as there were in 1905 from a hundred and sixty schools, most of which were decidedly inferior. This upward trend is probably warranted in the cases of many schools which have increased their faculties and facilities. In other instances

increased enrolments and graduates are probably not justified by proportional increases in staff and facilities.

Now the annual number of graduates far exceeds that of any period in the history of this country, approximating twice the number of physicians who die in normal years. This present large number of graduates is to be contrasted sharply with the figure for 1922, when only 2,500 received the M.D. degree. This figure—in all time low in medical graduates—was also related to war. It followed the low registration of freshmen in 1918 when less consideration was given to the necessity for continued training of physicians in wartime. Fortunately the last war ended relatively quickly, so that this lack of adequate medical preparation was not as much in evidence as it would surely be in the present conflict.

Current Comment

THE CONTROL OF DIPHTHERIA

The epidemiologic study of diphtheria by Russell¹ is of great significance with respect to the control of the disease. In the preface it is pointed out that, while progress has been made in reducing the deaths from diphtheria in England and Wales, the advance is disappointing in view of the fact that, of the infectious diseases of childhood diphtheria is the one of which exact biological knowledge is most complete and was earliest obtained. Russell's figures show a decline of nearly 60 per cent in the death rate from diphtheria in England and Wales during the past forty years, but this decline is 'unsatisfactory' compared with the reduction of 80 per cent of the mortality of diphtheria in white children aged 1 to 15 years in the United States between 1920 and 1938. In this decline in the United States active immunization of children against diphtheria is a factor of major importance. The number of children immunized in Britain before 1940 was small, but since then good progress has been made and at the end of 1942 46.5 per cent of the child population under 15 in England and Wales had been immunized. Russell discusses particularly the effects of active immunization on the incidence of diphtheria in New York City and Toronto. His summary follows:

There is very strong evidence that immunization particularly since the inclusion of preschool children has reduced the morbidity and the mortality from diphtheria in New York City and in Toronto. The statistical experience of diphtheria in these cities in the postimmunization period is significantly better than might have been expected from the trend or either the morbidity or the mortality in the preimmunization period. According to past experience the disease had a periodicity of six years in New York and of four years in Toronto. On this basis there should have been epidemics in both cities between 1930 and 1940 but none has occurred. The best explanation of this absence is that the health authorities in both cities by artificially immunizing the school and preschool children have prevented the occurrence of the epidemics.

Mass immunization in Canada and in the United States has saved thousands of lives which otherwise

¹ Russell W. T. The Epidemiology of Diphtheria During the Last Forty Years. Medical Research Council Special Report Series No. 47. London, 1943.

would have been lost. Present indications are that active immunization against diphtheria is the best means at hand to control the disease and should be used "on the widest scale possible."

"RECREATION—A RESOURCE OF WAR"

Recreation and relaxation are a definite contribution to the war effort.¹ Obviously the American people in these days cannot have the same kind or amount of relaxation or recreation that prevailed in normal times, many do not realize, however, that the opposite extreme—omission of recreation or relaxation—is detrimental to the war effort. A human being cannot exist continuously on an artificially high plane of productive effort or emotional tension. He must have release and relief, especially from the high intensity of machine production and from the psychologic strains of war. A pamphlet just made available by the Federal Security Agency tells what can be done toward community recreation by public agencies, private social agencies, labor unions, war plants, commercial enterprises and churches and in housing projects, dormitories and trailer camps. There is an extensive check list of recreational programs including social activities, active games and sports, music, arts and crafts. References are given, additional publications, and sources of further information. A more comprehensive report entitled "Spare Time—A War Asset for War Workers" describes the experiences of some communities and serves as an example of what might be done. Copies of this report can be had without charge by addressing the Division of Recreation, Office of Community War Services, Federal Security Agency, Washington 25, D. C.

POSTWAR EDUCATIONAL FACILITIES

Recognizing that large numbers of physicians will be seeking advanced training immediately after the war, the Council on Medical Education and Hospitals is making a careful study of the educational facilities in the graduate and postgraduate fields. A preliminary survey has already been instituted to determine what institutions and agencies will be able to expand their regular educational activities to meet additional postwar needs. Questionnaires were sent to all undergraduate and graduate medical schools, intern and residency hospitals, state medical associations, departments of health and other agencies interested in graduate or postgraduate education. The response has indeed been gratifying, for individual reports indicate that constructive planning is under way and that institutions are anxious to cooperate to the full limit of their facilities. The returns are not yet complete, but the available data are now being evaluated and will be supplemented by further studies in the near future, so that complete lists of facilities will be available to physicians returning from the war. These include hospital residencies, fellowships, basic science courses, graduate studies and short term refresher courses in the various branches of

medicine. Many physicians will wish to resume courses interrupted by the call to military service, while others will enter new training programs in preparation for general or special practice. Those who remain in military service after the war will be able to increase their professional training through the educational programs of the respective services. Even under wartime conditions, opportunities are being provided for specialty training in Army and Navy hospitals for which credit may be assigned by the individual certifying boards. The large number of physicians who return to civilian life will likewise find that the medical profession, the schools and the hospitals stand ready to meet the educational needs of the postwar period.

THE MEDICOLEGAL NECROPSY

In discussing the medicolegal necropsy in the symposium on legal medicine at the meeting of the American Society of Clinical Pathologists in Philadelphia, a year ago, Moritz¹ emphasized certain obvious shortcomings in law that hinder the use of the necropsy in the interest of public welfare. In most states, he pointed out, the statutory provisions for the medicolegal investigation of deaths under certain circumstances need to be revised and expanded. For the public good effective provision should be made for official, thorough investigation with necropsy in all deaths "known or suspected to have been caused or contributed to by mechanical, physical or chemical injury, all deaths occurring unexpectedly from obscure causes and all deaths known or suspected to be related to occupation." Investigators for these purposes should be selected on the basis of technical competence rather than politics, and of course the funds and facilities necessary for expert work must be provided. Moritz places the major responsibility for betterment of the low state of forensic pathology in nearly the whole of this country on the pathologists, because they know best what is needed. In planning for postwar medical services, opportunities to advance the usefulness of the medicolegal necropsy should not be neglected.

INFRA-RED TREATMENT OF ELECTRIC OPHTHALMIA

Recently infra-red radiation has been advocated as successful treatment of "flash" burns of the eye due to overexposure to ultraviolet emanation, the usual source being the welders' arc. The practice is at present being evaluated by competent observers. The Joint Committee on Industrial Ophthalmology of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology believes that a word of warning is warranted about the practice until additional supporting evidence is available. The harmful effects of any forms of radiation on the eye are sufficiently well known to suggest that physicians who treat flashed eyes refrain from using infra-red lamp treatment until the results of the present research work are made available.

¹ "Recreation—A Resource of War," a pamphlet publication of the Federal Security Agency, Division of Recreation Office of Community War Services, Washington 25, D. C.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

ARMY TAKES OVER TWO NEW YORK HOSPITALS

According to the Bronx Home News of July 12 the New Lebanon Hospital at Mount Eden Parkway and the Concourse New York City has been taken over by the Army Medical Corps for the duration. At the time of the dedication of the new hospital on June 6 it was equipped with 250 beds. Plans were made, however to increase this number to 400 in the near future. In addition to general medical and surgical wards there are five operating rooms, a fully equipped dispensary, pediatric division, dental clinic, special wards for the treatment of rheumatic cardiac cases and handicapped children and laboratories. The regular work of the hospital will be continued at the old hospital building at Westchester and Cauldwell avenues.

According to the New York Times of July 1 the Pilgrim State Hospital at Brentwood L I N Y has been leased by the War Department in view of making it a 1500 bed army general hospital. The hospital buildings will be remodeled at a cost of about \$2,000,000 and probably will be put in service by Feb 1, 1944.

BORDER SERVICE MEDAL FOR RESERVE OFFICERS

H R 2619 introduced by Foster Stearns of New Hampshire is aimed to correct an unintentional discrimination against medical reserve officers who were on active duty in the Army between Jan. 1 1916 and April 6, 1917 and who served elsewhere than on the Mexican border. This bill would make such medical reserve corps officers serving at that time eligible for the Mexican Border Service Medal. The present law makes National Guard officers who served during this period either on the border or elsewhere eligible for this medal. H R. 2619 would therefore right an injustice to the remaining few and now aged, physicians who rendered active service in 1916 and 1917 as officers of the old medical reserve corps as well as to any other member of a reserve component of the army not eligible under existing law to receive this medal.

THE NEWTON D BAKER GENERAL HOSPITAL

The War Department announced on June 17 that the new 1727 bed army general hospital under construction near Martinsburg, W Va. has been named in honor of the late Secretary of War, Newton D Baker. The hospital will occupy 180 acres located almost 4 miles southeast of Martinsburg the birthplace of Mr Baker. The hospital will cost about \$5,500,000.

MILITARY DENTAL WORK

Brig Gen. Robert H Mills chief of the Army Dental Corps recently announced that the Army is now turning out dentures at the rate of 60,000 a month and that 1,600,000 dental fillings are completed each month. More than 2,000,000 soldiers are treated for dental defects of some kind each month. The Army recently ordered 24,000,000 dental burrs with which to care for cavities in the teeth of military personnel. According to a press release from the American Dental Association on July 16 the

number of dental officers in the armed forces total 13,000, leaving 1 dentist for every 2,000 civilians in the country. Civilians were therefore advised to take all preventive dental measures possible in the way of mouth hygiene and of nutrition and thus relieve the load on the civilian dentist's shoulders. The civilian should not abandon his regular visits to the dentist but should make his appointments well in advance and then keep them. Civilians also were advised to adhere to a careful program of mouth hygiene and of nutrition. Brushing the teeth properly after every meal becomes a patriotic contribution in that it not only adds to working efficiency in wartime but preserves dental and general health as well.

MAJOR SPRONG RECEIVES THE AIR MEDAL

Major Aaron A Sprong flight surgeon with the Eleventh Group for nine months prior to his recent assignment to Strother Field, Kansas has received notice that the Air Medal will be conferred on him for meritorious achievement while participating in a flight last December 16 in the Solomon Islands. Before entering the Army Air Corps in June 1941, Major Sprong was a practicing physician at Sterling, Kan. Subsequently he was stationed at Randolph Field, Texas, and at Carlisle Barracks, Pennsylvania. He arrived in Hawaii in February 1942 whence he flew to Midway and was present throughout that furious battle. After Midway he flew back to Hawaii. From July 1942 until March 1943 he served in the Solomon Islands. Recently he was ordered to the homeland. Major Sprong graduated from the University of Kansas School of Medicine in 1934.

LIEUT COL PERRIN H LONG IN NORTH AFRICA

Dr Perrin H Long professor of preventive medicine at Johns Hopkins University School of Medicine Baltimore according to the Baltimore Evening Sun of July 10 is now a lieutenant colonel serving as medical director in the North African war theater. The North American Newspaper Alliance dispatch further concerned a front line treatment for nervous breakdowns which Lieutenant Colonel Long is said to have described as one of the greatest advances in military psychiatry during the war and also a great manpower saver. The type of case on which this treatment has been found effective was formerly erroneously called shell shock. Under the plan of treatment referred to some of the patients are sent back to duty on the second day, it is said and they usually ask to go back on the fourth day.

Dr Long served in the first world war as a private in the U S Army and was awarded the Croix de guerre. In view of his pioneer work with the sulfonamide drugs he was sent to Honolulu soon after the Japanese attack on Pearl Harbor to observe the effects of those drugs on the wounded.

FLIGHT SURGEONS' ASSISTANTS

A class of seventy nine flight surgeons assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine Randolph Field Texas July 3. Brig Gen Eugen G Remartz U S Army is commandant of the school.

MISCELLANEOUS

INCREASED PRODUCTION OF PENICILLIN

Additional facilities for the manufacture of penicillin have been acquired in Rensselaer, N. Y., by the Winthrop Chemical Company, Inc., according to Dr. Theodor G. Klumpp, president of the company. This drug is now allocated exclusively to the armed forces, millions of units being supplied weekly. The "unit" system of measurement derives from Oxford University. Pure penicillin has not yet been isolated. The "Oxford unit" is based on comparison with standard material furnished by Oxford University to laboratories throughout the world. One million units weigh about $\frac{1}{2}$ ounce. Sulfonamide resistant cases of gonorrhea can be cured promptly by as little as 100,000 units of penicillin. Larger doses are usually needed for osteomyelitis and other infections.

Penicillin was discovered by Dr. Alexander Fleming, English scientist, in 1929. It was not then available for treatment of disease because of the extremely small quantities that could be produced and the instability of the substance. The present interest in penicillin dates from 1939, when important information regarding the chemistry of the extract was obtained and it was found that the calcium and sodium salts are more stable than the parent substance. The exact structure of penicillin is unknown at present, and until it has been determined artificial production by synthesis is impossible. However, much has been learned about the "empirical" or general chemical formula.

Penicillin is now under strict allocation of the War Production Board for national defense and there is no prospect that a surplus will soon be available for civilian use.

NURSING DIVISION FOR PROCUREMENT AND ASSIGNMENT SERVICE

The Nursing Supply and Distribution Unit of the War Manpower Commission has been made the Nursing Division of the Commission's Procurement and Assignment Service, Paul V. McNutt, chairman of the commission, announced on July 27.

"The objectives of the Nursing Division," Mr. McNutt explained, "are the same as those divisions of the Procurement and Assignment Service now dealing with the dentist, veterinary, physician and sanitary engineer for their professions. They involve the recruitment of sufficient nurses to meet the needs of the armed forces and the provision of minimum adequate nursing care for the civilian population, nonmilitary governmental agencies and industry."

Recommendations regarding the operation of the nursing division will be made to the Directing Board of Procurement and Assignment Service, headed by Dr. Frank H. Lahey, Boston, by a nursing advisory committee. The nursing division is represented on all the present advisory committees to the directing board that are concerned with problems that affect nurses. Miss Katherine Tucker, Philadelphia, and Miss Laura Grant, New Haven, Conn., have been appointed to the directing board.

Miss L. Louise Baker has been named an assistant executive officer of the Procurement and Assignment Service to work under the general direction of the directing board, and Dr. Maxwell Lapham executive officer. She will have the responsibility of carrying out the functions of the nursing division and will be assisted by Miss Ruth A. Heintzelman. The already existing technical, clerical and statistical sections of the Central Office of Procurement and Assignment Service will be utilized, and four nurse consultants will be added to the staff to supervise the work in the field.

The activities of the nursing division in the field will be carried out by separate state and local committees. The Supply and Distribution Committee of the State Nursing Councils for War Service, representing the various nursing organizations in each state and serving without compensation, will act as the state committee for nurses for the Procurement and Assignment Service, and the local nursing council for war service will act as the local committee in each community. Both state and local committees will function independently of but in cooperation with the state committees for physicians of the Procurement and Assignment Service.

CONFERENCE ON VENEREAL DISEASE PROGRAM

Representatives of the Anglo-American Caribbean Commission and members of the Interdepartmental Committee on Venereal Disease held a three day conference in Washington late in June to consider the inauguration of an adequate program for control of venereal disease in the Caribbean area. The conference was attended by representatives of the British government, of the U. S. Army, Navy, Public Health Service, State Department, Federal Security Agency, Federal Works Agency and Bureau of the Budget of the Rockefeller Foundation and of the American Social Hygiene Association.

Although the present programs for venereal disease control in Puerto Rico and Panama have brought about a reduction in infection rates, there is great need for expansion of facilities and additional trained personnel in these areas. In the Trinidad area, however, there has been apparently no program of venereal disease control and the inauguration of one will involve, literally, according to Dr. N. M. MacLennan, Great Britain's director of medical services in Trinidad, working from the ground up and our U. S. Army and Navy officials now working in that area corroborated his opinion. Public health legislation is also needed as a foundation for adequate control measures in Trinidad. The proposed budget for an immediate control program in Trinidad would set up a fund for establishing clinical service there and a well equipped laboratory, staffed by physicians, nurses and technicians recruited when possible from the native personnel. The establishment of the proposed plan for Trinidad would need a budget for the first year of about \$200,000 to be divided between Great Britain and the United States. The necessary expansion of the existing programs in Puerto Rico and Panama could be accomplished by yearly budgets of \$480,000 and \$300,000 respectively, it was estimated.

The last day of the conference was devoted to discussion on malaria control in the Caribbean area with the object of developing a coordinated plan for the control of malaria in both the armed forces there and in the civilian population.

RESTRICTION ON MANUFACTURE OF MEDICAL FURNITURE

The War Production Board issued on July 13 Schedule 3 to General Limitation Order L-214, placing restrictions on the manufacture of items and models of medical and surgical furniture and related equipment. This order provides, among other things, that no manufacturer shall make or continue to make any items of such equipment and furniture other than those on list A attached to the schedule, and the listed items shall be made only in the number of models specified on the list which conform with the descriptions set forth. However, a manufacturer may make any number of models of medical and surgical furniture and related equipment not listed on list A and any number of models and items on list A in excess of the number specified provided they do not contain any metal other than iron and carbon steel and that the weight of such metal comprises not more than 25 per cent of the total weight of the model. No manufacturer shall incorporate in any medical and surgical furniture and related equipment any stainless steel or other alloy steel, monel metal, copper, copper base alloy, nickel, aluminum or zinc, except as specified in list A. This restriction does not apply to the use of copper and copper base alloy in the electrical circuit or electrical connections of any items listed in list A.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America with headquarters at 420 Lexington Avenue, New York, has launched a campaign for medical supplies to be parachuted to guerilla bands in France in answer to an appeal by Capt. Douglas Smith, French Foreign Legion representative at Gen. Charles de Gaulle and Georges Catroux. A goal of one thousand surgical kits for units of twenty-five men, and twenty-five thousand individual first aid kits has been set.

PUBLIC HEALTH UNDER HITLER

According to NDZ, Germany, of February 24 the call up of doctors and *feldschers* for service at the front has made it necessary to increase the number of women employed on youth welfare work and in the wartime health services. A large proportion of this work is done by the Health Service Girls of the HJ, whose training was considerably extended last year. On principle, all 16 year old girls receive an appropriate basic training consisting in the general structure of the body, hygiene, health and physiology, and first aid. This training which is carried out in twelve lectures of two hours each is in the hands of efficient doctors and members of the DRK. By passing the final test the girl acquires the title of Health Service Girl. Then follow the Working Groups for Health Living or the Faith and Beauty Scheme of the BdM, which provide additional training in the fields of nutrition and nursing. Over 73 000 girls were trained and became Health Service Girls last year a considerable increase compared with the previous years. In all, 175 000 Health Service Girls are now available.

Transocean news agency, June 13 reports from Berlin that a number of institutes have been established in the eastern regions occupied by the German forces to combat epidemic diseases. These institutes are to protect German soldiers and civilians. Of the greatest importance is the German Hygienic Institute for the Ostland at Riga which is equipped with all modern apparatus, mobile and stationary bacteriologic field laboratories, several mobile delousing trains and others for producing drinking water. The institute also has trains fitted with everything necessary for the medical examination of the population even in the remotest part of the Ostland. The institute has a department for medical research and another for training practical helpers in fighting diseases. Similar institutes were also opened at Kiev and at Kherson. The latter is chiefly concerned with fighting malaria.

In order to save lives which are being lost owing to the shortage of German specialists the German Volkshilfe has established six maternity homes at Zemun, Indjija, Ruma, Vinkovci, Djakovo and Verec according to the *Deutsche Zeitung* in Kroatin Yugoslavia of May 23. The home at Verec must be closed for an indefinite period because the locality is unsafe. These homes have been established primarily for Volksdeutsche women who are expecting children under difficult conditions in small far away settlements where they are in continuous danger or are continuously being attacked by the bandits.

According to DNB, Germany, June 5 the war has considerably intensified the need for blood donors and in order to meet it the SA, members of which formed the core of the official blood donors' organization even before the war, has increased its efforts in this respect. The Hansa Group of the SA alone has till now given 190 623 cc of blood and many other groups have reported similarly high figures. The Berlin-Brandenburg group has 2 900 blood donors for the armed forces alone at its disposal. The list of donors is headed by an *obersturmfuhrer* of the SA, who has given a total of 74 520 cc of blood on 191 occasions.

According to Transocean, June 11, the former dean of the Leningrad Medical Institute and head of the surgical department, Prof W. Schaak, has been appointed chief physician of Potsdam Municipal Hospital. Schaak was looked on in Soviet Russia as one of the greatest specialists in surgery. In April 1942 he was evacuated from Leningrad to Kislovodsk. When the German troops in the summer of 1942 approached the Kislovodsk area Schaak succeeded in reaching the German medical corps. Up to his appointment to the Potsdam hospital Professor Schaak served as a surgeon in a German field hospital.

According to NPD of May 29 a special German-Russian medical dictionary has been published for all doctors and officials employed in the health service in the East. This will facilitate the comprehensive work of the German doctors for the Russian civil population.

DNB (for Europe), June 8, reports from Riga that in the Districts General of Estonia, Latvia and Lithuania a new law comes into force on July 1 replacing the existing Bolshevik law on health and combined health and accident insurance, which closely follows German law. Considerable improvement is achieved, particularly where insurance grants are concerned. In each of the Districts-General an independent health insurance office will be set up as part of the autonomous administration.

Pester Lloyd Hungary, of May 7 states that in April there were 27 cases of typhus in Budapest, and 11 cases of endemic typhoid were brought from the country to the Budapest hospitals.

Sari Bor writes from Breslau according to the *Magyar Nemzet* of May 5 that. The people of Breslau vigorously protest against the suggestion that there is a peaceful atmosphere in the town. They are perfectly justified in doing so, for, although owing to its favorable situation the town has had little direct experience of the war air raids are not unknown even here. The people have simply suffered more seldom and less from them than the people of most German towns.

According to *Pester Lloyd* Hungary, of May 4 the minister of agriculture has made the inoculation of pigs against plague obligatory in the counties of Barcs, Hont, Csik, Csongrad, Esztergom, Heves, Kolozs, Nograd, Szabolcs, Udvarhely and Ung and in the municipalities of Ungvar (Uzhhorod) and Komárom (Komarno).

All the more active is the war effort in the old capital of Silesia in other spheres. As the most easterly metropolis in the reich it is the first place at which the hospital trains from the Russian front arrive. At the present time the town is looking after 160 000 wounded. It deals with this gigantic task for the most part from its own resources with its own doctors and with enormous numbers of voluntary nurses. There are doctors who are on the street from dawn till late in the evening before they can get through their days work in the six or seven hospitals with which they are concerned.

According to *le Journal* May 25, French and German medical services inspecting Frenchmen working in Germany made distressing observations. The third contingent of the "releves" will mobilize 220 000 workers for Germany and 180 000 for the Todt Organization in France. Heretofore the percentage of sick and unfit did not exceed normal limits but today there has been an enormous increase. Those registered as invalid in Paris were over 50 per cent and in the provinces 36 per cent. Those escaping labor conscription owing to ill health are chiefly suffering from tuberculosis and syphilis.

According to Radio Lyons June 24 a law has been published regulating the medical protection of French workers in Germany. Doctors, chemists and dentists will be mobilized as well as students of medicine, pharmacy and dental surgery. Persons liable to mobilization will be designated by the High Council for Medicine and Pharmacy.

Sjds-enska Dagbladet Malmö May 23, reports that there are about three hundred doctors aged 80 and over and three thousand aged 70 and over in practice in Germany.

Radio Lyons June 10 reports that the Regional Councils of the Medical Profession (*Ordres de medecins*) will take a census of medical vacancies caused by the ban on foreign doctors who are forbidden to carry on their practice. Vacancies will be reserved for French doctors who are at present prisoners of war and put forward an application to this effect.

NPD Czechoslovakia June 3 reports from Bratislava that the birth rate in Slovakia has risen by 80 per cent since 1939 which is mainly due to the introduction of family allowances.

ORGANIZATION SECTION

OFFICIAL NOTES

HEALTH EDUCATORS VISIT A M A HEADQUARTERS

Twenty-seven young women holding fellowships in health education for training at the University of North Carolina, made possible by the W K Kellogg Foundation, Battle Creek, Mich., through a grant to the United States Public Health Service, spent the week of August 2 to 6 at the headquarters of the American Medical Association in classes and demonstrations of the health education work of the Association. Such demonstrations, authorized by the Board of Trustees of the American Medical Association, are under the direction of the Bureau of Health Education. The visit to the American Medical Association was part of a three month assignment of field

training in connection with the fellowship courses. From the American Medical Association the group went to the Cleveland Health Museum, where they will spend the rest of the month of August.

SUMMER HEALTH HINTS

The last program for the series of broadcasts over WLS on Thursdays at 2:45 under the title "Summer Health Hints" will be

August 19 "Hay Fever Time"

A new series of broadcasts on appropriate, timely health topics is contemplated on station WLS beginning in early autumn.

THE CURRENT TAX PAYMENT ACT OF 1943

Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association

The first step to put federal income taxpayers on a pay as you go basis, under the Current Tax Payment Act of 1943, approved by the President on June 9, was taken on July 1, when the withholding features of the new act became effective. Since that date employers have been required to withhold 20 per cent of the compensation paid employees in excess of withholding exemptions of \$624 for single persons, \$1,248 for married persons or heads of families and \$312 for each dependent.

GROUPS EXEMPTED FROM WITHHOLDING

Designated groups are exempted from the withholding procedure, namely (1) members of the military and naval forces, (2) agricultural workers, (3) domestic employees, (4) casual employees, (5) United States citizens or residents working for a foreign government, including the Philippines, (6) non-resident aliens except, unless exempted by regulations, Canadians and Mexicans, (7) United States citizens or residents if the major part of the work done by them for the employer during the calendar year was done outside of the country and (8) ministers of the gospel.

METHOD OF WITHHOLDING

Employers may follow one of two methods in withholding the tax. They may compute with exactness the amount, that is, 20 per cent of the wage or salary above exemptions, or they may withhold in accordance with wage groupings contained in tables incorporated in the act. Most employers will use the latter method because of its simplicity. The use of the tables, however, will in some instances result in overwithholding, but the excess withheld may be adjusted when the taxpayer files his final return, as he must do on or before March 15, 1944.

DISPOSITION OF WITHHELD TAXES, REPORTS

Physicians who are employers have since July 1 been withholding the 20 per cent tax from the wages of employees who come within the withholding provisions of the act. If a total of more than \$100 is withheld during any month, the amount withheld must be transmitted, within ten days after the close of the calendar month, to a depository authorized by the Secretary of the Treasury, the names and addresses of these may be obtained from any bank. Physicians who withhold less than \$100 a month must make quarterly returns on form W-1 to their collectors of internal revenue, showing the aggregate amount of taxes withheld during the quarter. This return must be filed on or before the last day of the calendar month following the close of each quarter and must be accompanied by the payment of the full amount of the tax withheld. The first return will be due not later than Oct. 31, 1943, covering the months of July, August and September.

Physicians must furnish each employee a "Statement of Income Tax Withheld on Wages" (form W-2), to be delivered to the employee on or before January 31 next. If employment terminates before the end of the year, the statement must be furnished within thirty days of the date on which the last payment is made. Duplicate copies of such statements must be retained by physicians and transmitted to the collector of internal revenue with the final return for the fourth quarter of the calendar year. All forms may be secured from the collector's office. Physicians should obtain from the same source a copy of circular WT, which will explain in detail the duties imposed on employers in connection with the withholding process, the types of records to be kept and the various kinds of reports to be made.

PHYSICIANS WHO ARE EMPLOYEES

Physicians who are employed on a salary basis went on a current tax payment basis, July 1. They normally need not concern themselves with the procedure. They will be furnished by their employers all statements to which employees generally are entitled. Many such physicians, however, will be required to file on or before Sept. 15, 1943, a Declaration of Estimated Tax and will be required together with all other taxpayers to file a final return for 1943 on or before March 15, 1944, at which time necessary adjustments of taxes can be made.

DECLARATION OF ESTIMATED TAX

The withholding procedure has placed on a current payment basis an estimated fifty million federal income and victory tax payers. There remains another group, the self-employed and employees expressly exempted from the withholding process, who are yet to be placed on a pay as you go basis. To accomplish that end, a second step must be taken on or before Sept. 15, 1943, when the following persons will be required to file with the collector of internal revenue a Declaration of Estimated Tax covering the calendar year 1943.

1 Single or married but not living with a spouse at the date prescribed for the making of the declaration (whether or not head of a family), if he had for the taxable year 1942, or reasonably expects to have for the taxable year 1943, (a) gross income of more than \$2,700 from wages subject to withholding, or (b) gross income of more than \$100 from sources other than wages subject to withholding, and also gross income of \$100 or more from all sources.

2 Married and living with spouse at the date prescribed for the making of the declaration, if he had for the taxable year 1942, or reasonably expects to have for the taxable year 1943, (a) gross income from wages subject to withholding, when added to gross income from such sources of his spouse,

exceeds \$5,500, or (b) gross income other than from wages subject to withholding which when added to gross income other than from such wages of his spouse exceeds \$100, and also his gross income from all sources exceeds \$24 for 1943 or the aggregate gross income from all sources of both spouses amounts to \$1,200 or more for either 1942 or 1943.

Individuals regardless of marital status who were required to file an income tax return for the taxable year 1942 and whose wages subject to withholding for the taxable year 1943 are reasonably expected to be less than such wages for the taxable year 1942.

CONTENTS OF DECLARATION

With relatively few exceptions all physicians will be required to file the declaration. Forms for use in filing the declaration have not been released, but it is understood that they will be mailed to taxpayers on or before September 1. They will be short and will differ materially from previous income tax returns. On them the taxpayer will merely state the amount of his estimated income tax and net victory tax liability for the year, based on the estimated income and deductions and allowing for the current credit against the victory tax liability to be explained later, in case the taxpayer elects to take the credit currently. From the estimated taxes due there may be subtracted the two installments already paid in 1943 any amount in the case of employees withheld during the year on account of the victory tax as such and on account of the 20 per cent withholding that went into effect July 1 together with estimated amounts that will be withheld during the remainder of the year. The difference will represent the remainder of the tax due on account of 1943 income. One half of the total tax due must be paid when the declaration is filed and the remainder on or before December 15, subject to the right of a taxpayer in service to postpone payment if his ability to pay is materially affected by reason of his service.

While the declaration will be short, it will be necessary for most physicians to compute their taxes in the same manner in which computations have been made in the past. There has been no change in rates and no change in exemptions and deductions except in the case of taxpayers in the armed forces. Physicians therefore, may rely on the statement that was published in *THE JOURNAL*, Jan. 30, 1943 for suggestions as to the credits and exemptions that may be claimed. The change that has been recently made relates solely to the method and time of the payment of victory and income taxes.

Form 1040-ES will be used in filing the declaration. Complete instructions will accompany the form when it is sent to taxpayers, including a table that will aid in the computation of estimated income and victory tax for 1943 on incomes not over \$10,000. A careful study of the instructions will simplify the procedure of completing the declaration.

UNDERESTIMATED TAX PENALTY

The actual income and deductions can be accurately computed by physicians for the part of the calendar year immediately preceding the filing of the declaration for the remainder of the calendar year estimates must be carefully made in view of the penalty of 6 per cent that attaches if the estimated tax proves to be 20 per cent less than the tax actually due. It is before December 15, a taxpayer discovers that he has underestimated his tax by more than 20 per cent he should on that date file an amended declaration, correct his mistake and avoid the possibility of penalty.

SUBSTITUTION OF 1942 TAX

Having estimated his 1943 tax liability on the basis of actual and anticipated 1943 income exemptions and credits the physician who is not in service must then compare the estimated tax with the 1942 tax computed last March. If the 1942 tax was greater he must enter the 1942 tax on the declaration and pay that tax instead of the 1943 estimate. In order to prevent any advantage accruing to taxpayers by reason of the shut to a pay as you go basis, the law provides in effect that the current 1943 tax liability shall not be less than the 1942 liability. This does not apply to taxpayers who are in the armed forces as will be explained later.

ABATEMENT OF TAX

To prevent an undue doubling up of taxes as a result of the change to a current collection basis, the law provides for an abatement of 75 per cent of one year's tax, or the first \$50 thereof, whichever amount is the greater. The abatement is based on the lower tax of the two years, except in the case of taxpayers in service. If the 1943 tax is lower 75 per cent of it will be abated. If the 1942 tax is lower 75 per cent of it will be abated. Physicians need not give this abatement procedure any concern at the time the declaration is filed. The 25 per cent unabated portion of the tax will become a liability on March 15, 1944, when the final return for 1943 is filed. The unabated portion may then be paid in full or one half must be then paid and the remaining half paid on or before March 15, 1945.

THE VICTORY TAX

The Revenue Act of 1942 imposes a special victory tax on individuals amounting to 5 per cent of their victory tax net income. This tax is in addition to all other taxes imposed by the act applies to income received after Dec. 31, 1942 and will continue in effect for the duration of the war unless sooner repealed. A discussion of this tax as it relates to the medical profession was published in *THE JOURNAL* Dec. 5, 1942. That discussion, however, emphasized the withholding of the tax by physicians from the wages of employees and the withholding of the tax from the salaries of physicians who are themselves in an employee category. Physicians now must estimate the amount of the victory tax they themselves must pay during the calendar year 1943 and report that amount on the declaration to be filed on or before September 15.

VICTORY TAX GROSS AND NET INCOME

The 5 per cent victory tax is imposed not on the taxpayer's net income that serves as a basis for normal and surtaxes but on his victory tax net income. Many of the deductions allowable from gross income to arrive at net income for income tax purposes are not allowable in determining net income for victory tax purposes. Physicians should keep that fact in mind in estimating the special tax.

Gross income for victory tax purposes includes all income except (1) gain from the sale or exchange of capital assets, (2) interest on United States government obligations allowable as a credit for income tax purposes and (3) compensation for injury or sickness includible otherwise as a part of gross income because of a deduction claimed for medical expenditures. Victory tax net income is gross income minus the following exclusions: 1. Business expenses allowable generally for income tax purposes. 2. Interest and taxes only to the extent incurred in carrying on a trade or business or incurred for the production or collection of income or for the management, conservation or maintenance of property held for the production of income. For ordinary income tax purposes interest and taxes are deductible even if incurred for personal purposes as, for example, interest on personal loans and taxes on property used as a home. (3) Uncompensated losses sustained during the year if incurred in a trade or business. Losses from wager transactions may be excluded only to the extent of the gains from such transactions. 4. Depreciation, depletion, amortization, pension trust contributions, alimony payments (to the extent deductible for ordinary income tax purposes) and certain other exclusions not of particular concern to physicians. Charitable contributions are ordinarily not deductible from gross income for victory tax purposes. In the case of a taxpayer who uses the simplified return form his victory tax net income is his gross income.

VICTORY TAX EXEMPTION

From the victory tax net income a specific exemption of \$24 is allowed each taxpayer as a credit, irrespective of his marital status. There is no other personal exemption. The liability on account of the victory tax therefore will be computed on the basis of 5 per cent of the victory tax net income after the \$24 credit has been taken and the amount so computed must be included in the declaration to be filed on or before September 15.

VICTORY TAX WITHHELD

Amounts withheld from the salaries of physician employees during the year on account of the victory tax may be credited against the computed tax. For the first half of 1943 5 per cent was withheld for victory tax purposes. Since July 1 the 20 per cent withholding includes 17 per cent for income tax purposes and 3 per cent for victory tax purposes, it being assumed that most taxpayers subject to withholding will take advantage currently of the postwar credit, later to be discussed, and that therefore the 3 per cent will cover the net victory tax due. Physician employees, however, will not be required when they file their declarations to break down the 20 per cent withholding to indicate the amount withheld for income tax purposes and for victory tax purposes.

POSTWAR CREDIT OR REFUND OF VICTORY TAX

As pointed out in THE JOURNAL for Dec 5, 1942, the Revenue Act of 1942 provides that as soon as practicable after the date of cessation of hostilities the following amounts of victory tax paid for each taxable year will be credited against any income tax payment or installment thereof then due from the taxpayer and any balance will be refunded immediately.

1 In the case of a single person or person married but not living with husband or wife, 25 per cent of the victory tax or \$500, whichever is the lesser.

2 In the case of the head of a family, 40 per cent of the victory tax or \$1,000, whichever is the lesser. In the case of a married person living with husband or wife where separate returns are filed by each, 40 per cent of the victory tax or \$500, whichever is the lesser. In the case of a married person living with husband or wife where a separate return is filed by one spouse and no return is filed by the other spouse, or in case of a husband and wife filing a joint return, only one such credit will be allowed and such credit may not exceed 40 per cent of the victory tax or \$1,000, whichever is the lesser.

3 For each dependent, excluding as a dependent in the case of the head of a family one who would be excluded as a dependent for income tax purposes, 2 per cent or \$100, whichever is the lesser.

If during the taxable year the status of the taxpayer (other than a taxpayer whose gross income is \$3,000 or under and who uses the simplified return form) changes with respect to his marital relationship or with respect to his dependents, the amount of the credit or refund on the victory tax for the year will be apportioned under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury in accordance with the months prior to and after the change. For the purpose of such apportionment the fractional part of a month will be disregarded unless it amounts to more than one half of a month, in which case it will be considered as a month.

CURRENT CREDIT FOR POSTWAR REFUND

A taxpayer may, when he files his declaration on September 15, take credit currently for the postwar refund of the victory tax to which he would be entitled after the war. The law provides that there may be allowed as a credit against the victory tax, to the extent of the postwar credit (1) the amount paid by the taxpayer during the year as premiums on life insurance, in force on Sept 1, 1942 on his own life, on the life of his spouse or a dependent, less the amount of dividends received from such insurance, (2) the amount by which the smallest amount of indebtedness of a taxpayer outstanding at any time during the period beginning Sept 1, 1942 and ending Dec 31, 1942 exceeds the amount of indebtedness of the taxpayer outstanding at the close of the taxable year, and (3) the amount by which the amount of obligations of the United States owned by the taxpayer on the last day of the taxable year, or Dec 31, 1943, exceeds the amount of such obligations owned by the taxpayer on Dec 31, 1942.

If the taxpayer owns an obligation of the United States jointly with one other person, he will be entitled to full credit for the amount of the obligation only in case he himself paid for it. The term "obligation of the United States" means United States saving bonds, series E, F and G. The term "amount of obligations" means the amount paid for the obligations. The term "owned" means acquired by purchase.

An example may serve to clarify. Dr A, an unmarried physician with no dependents, at the time he files his declaration on September 15 estimates that he will owe a victory tax of \$100. During 1943 Dr A had purchased United States saving bonds, or paid premiums on life insurance, or reduced indebtedness, expending a total of \$1,000 for such purposes. Dr A may pay the victory tax of \$100 during 1943 and after the cessation of hostilities obtain a refund or credit of 25 per cent of the tax, or \$25, the percentage of credit that will be allowed a single person. Or, when he files his declaration he may reduce his victory tax by taking credit for the amount expended for bonds, insurance premiums or reduction of indebtedness, but only to the extent of the postwar credit to which he would be entitled after the cessation of hostilities, that is, \$25. In one case Dr A pays the full victory tax of \$100 and gets a refund or credit later, in the other case he pays \$75 and will not thereafter receive a credit or refund.

PHYSICIANS IN MILITARY AND NAVAL SERVICE

While the Current Tax Payment Act does not refer to taxpayers in service in connection with the filing of declarations, it is understood that the requirements heretofore existing as to the necessity of filing regular income tax returns will be extended to declarations. Physicians in service, therefore, should comply promptly with the new requirement, but if they are on duty outside the United States they may delay filing the declaration until after the war or until after their separation from the service, whichever may be earlier.

The requirement in the new act that taxpayers must in effect pay for 1943 a tax equal to the higher tax of the two years 1942 or 1943 does not apply to taxpayers in service. As explained in House Document No 237—Current Tax Payment Act of 1943. Questions and Answers—this special relief provision for taxpayers in service will be applied as follows.

Members of the armed forces do not have to pay on the higher of the two years 1942 or 1943, with respect to that portion of the 1942 tax which is attributable to "earned" income (i. e., from wages or salary) not in excess of \$14,000. Thus, if a soldier earned \$3,000 in 1942 as a civilian, incurring a tax liability of say \$300 and has no tax liability on his 1943 service pay he would not be required to increase his 1943 liability by the excess of the 1942 tax over the 1943 tax. In effect, his 1942 liability is completely abated.

On the other hand, if part of the serviceman's 1942 tax was attributable to "unearned" income and part to "earned" income (i. e., income from investments or wage and salary income in excess of \$14,000) the 1943 tax will be increased by the amount by which the tax on the "unearned" portion of the 1942 income exceeds the 1943 tax. For example, suppose a single man had a civilian salary of \$15,000 in 1942 and had income from rents, dividends and interest amounting to \$5,000 on which the total tax was \$6,800. In 1943 he went into the Army as an officer and receives a service pay of \$2,400. His final 1943 tax liability would be computed as follows.

He would figure the tax on his 1943 service pay, after excluding from consideration the first \$1,500 thereof under the provisions of the new law. The resulting 1943 tax would be approximately \$80. He would then add to his 1943 tax liability the excess of the 1942 tax over the 1943 tax, after deducting from such excess the amount by which the 1942 tax was increased by reason of the inclusion of the first \$14,000 of the amount of the "earned" net income in 1942. He finds that the 1942 tax exceeds the 1943 tax by \$6,720 (\$6,800 minus \$80). He recomputes the 1942 tax to see how much of this excess was due to the inclusion of the "earned" income (i. e., from wages or salary) up to \$14,000. Subtracting from the 1942 income all salary income not in excess of \$14,000 would leave \$1,000 of the salary income and the \$5,000 of investment income, or a total of \$6,000 on which the tax would be approximately \$1,200. This shows that the 1942 tax was increased by \$5,600 (the excess of \$6,800 over \$1,200) by reason of the inclusion of the "earned" income up to \$14,000. Therefore the \$5,600 is subtracted from the \$6,720 excess of the 1942 tax over the 1943 tax, leaving a balance of \$1,120, which is the amount to be added to the tax on 1943 income in computing the final 1943 liability of the serviceman in question. His total 1943 liability, therefore, would be \$80 (the tax on his 1943 service income) plus \$1,120 (the excess of the 1942 tax attributable to "unearned" income over the 1943 tax) or a total of \$1,200.

This is the amount he would include in his Declaration of Estimated Tax for 1943. In this instance he still pays on the higher of the two years after eliminating from the 1942 income all wage and salary income up to \$14,000. The serviceman in question would also owe the unabated portion of the lesser year's tax, 25 per cent of the 1943 liability of \$80 in this case or \$20.

SPECIAL EXEMPTION FOR MEMBERS OF ARMED FORCES

The new act declares nontaxable the first \$1,500 of the service pay of members of the armed forces, including commissioned officers. Under the prior law, servicemen below the grade of commissioned officers were permitted to exclude from gross income the first \$250 of their annual pay.

and the first \$400 if married. In effect the new law raises the per cent exemption of servicemen to \$2,000 if single and \$2,700 if married plus \$500 for each dependent.

CANCELLATION OF TAX ON DEATH OF SERVICEMEN

Any tax liability owed by a member of the military or naval forces who dies in active service is canceled the provision being retroactive to Dec. 7, 1941. If the tax has already been assessed it will be abated and if the tax has already been collected it will be refunded as in overpayment. This tax forgiveness applies only to income taxes, not to the estate tax. In view of the \$60,000 exemption from estate tax liability

possibly it was assumed that the estates of most deceased servicemen would not be liable to the estate tax.

FINAL RETURN FOR 1943

Taxpayers will be required to file on or before March 15, 1944 a final return for 1943 when necessary adjustments can be made. At the same time an estimate for 1944 taxes must be made. The final return for 1943 and the estimate for 1944 will be made. It is understood on a single form. Taxpayers not subject to withholding will be permitted to pay their 1944 taxes quarterly, the first payment being due when the estimate is filed.

WOMAN'S AUXILIARY

Arkansas

Dr. Herbert K. Abrams of the Miller County Public Health Service was the chief speaker at the public relations meeting of the Bowie-Miller County medical auxiliary recently. Representatives of the parent teacher associations were among the guests.
